Persuasion Niche and Political Messaging

A persuasion niche is a niche market that is the target for a specific persuasive message tailored or best suited to that niche as part of a marketing or political messaging endeavor. In the private sector, a niche market is the subset of the overall market at which a product is aimed, but in politics, the "market" for a political product—whether a candidate, ballot issue, or cause—consists of all eligible voters. In political campaigning and messaging, "niche market" refers not to the market at which the overall campaign is aimed, but to a smaller and clearly defined subset to which some approaches and aspects of the product will be more appealing than others.

A simple example is the energy conservation campaign, which has taken numerous approaches to convincing audiences to use less electricity, appealing to some with environmental concerns (the lesser damage wrought by more conservative fuel use), to others with economic concerns (using less electricity is less expensive, despite one's opinion of global warming), to still others with foreign policy concerns (diminishing dependence on foreign oil), or the very specific side effects of the overuse of electricity, such as light pollution and its effect on stargazing. In marketing, this is also called precision marketing,

which emphasizes not general or universal points of appeal about a product or message, but the specific relevance of the message to specific elements of the public.

Political niche markets are often defined in geographic or demographic terms, such as mountain state voters; voters in Oxford, Mississippi; young voters; Hispanic female voters; independent voters; or non-Hispanic white voters over 65 years old. How large a target can be while still being a "niche" is essentially a function of the scope of the campaign. A local political campaign is already aimed at a relatively small number of voters; for instance, compared to a statewide or national campaign. Likewise, a primary campaign is focused on a relevantly different group of voters than a general election is (i.e., a group that may be more persuadable if the candidate affirms his or her commitment to party ideas than by a candidate who, during the general election, emphasizes his or her moderate stances and willingness to work with the other side). Primary candidates with a reasonable expectation of nomination may bear general election voters in mind even during the primary, to avoid making or supporting statements that could be used against them by their general election opponent.

The larger the scope of a campaign, the more diverse the group of voters to which it is marketed, which—as with the energy conservation example—necessitates emphasizing different (not contradictory) messages in order to reach different segments of the population. This is not a new phenomenon; even the earliest American political campaigns had to deal with the very different political concerns of the free north and the slaveholding south, and the different lives and economic realities of urban Americans and rural farming Americans that constituted the earliest rebels against the new American government. More recently, various Democratic congressional re-election campaigns in 2010 and 2012 focused on the specific benefits of health care reform that were being or would be reaped by different segments of the candidates' constituencies.

Internet and Niche Messaging

The Internet has made niche marketing a more popular technique throughout the public and private sectors. The 2008 Barack Obama campaign

was especially forward thinking in the way it tracked the different results of differently worded fundraising e-mails, not only in terms of each draft's relative efficacy, but also its appeal across different niches. The discovery of untapped niches, or niches that can be leveraged to one's favor, is an important part of the field. An important related concept is that of the "long tail"—the subset of a set of objects that is distributed far from the center of its distribution. When political campaigns are targeting the same groups of voters, the center of distribution, it is advantageous to find ways to attract or persuade voters in the long tail.

Niche marketing is easier online, where messages can be precisely narrowcast at target markets, instead of broadcast at large audiences like on television or on billboards. The overwhelming majority of American adults are regular Internet users and have regular contact with both e-mail and online advertising. Al Franken's 2008 senatorial campaign was one of the first to provide a case study of persuasion niche marketing, targeting, or "nanotargeting" (in the parlance of the campaign, referring to the very small and tightly focused nature of the marketing efforts) more than 125 different niche groups for less than \$100,000, resulting in 2,500 separate donors, 20,000 clicks, and 5,500 e-mail signups.

Persuasion niche marketing is very specifically targeted, not only according to demographics, but also by issue. The Franken campaign tied different Google ads to very specific keywords so that they would be triggered by searches, or in the case of Gmail users, e-mails containing the relevant phrases. These keywords represented various issues of concern to the targeted niche groups. Franken's strongest campaign material—his or her various positions, articles on Franken, and endorsements—were paired with the niche groups for which they would be the most persuasive, and the ad campaigns were accordingly arranged.

Petraeus, David

In November 2012, David H. Petraeus, director of the Central Intelligence Agency (CIA) and a retired four-star general, resigned after revelations that he had engaged in an extramarital affair with Paula Broadwell, his biographer. The affair came to light during a federal investigation into threatening e-mails Broadwell sent to a social acquaintance of Petraeus, who Broadwell perceived to be a competitor for his affections. Petraeus's resignation ended a decades-long career during which he was instrumental in reviving and applying counterinsurgency strategy in the wars in Iraq and Afghanistan.

Biography

David H. Petraeus was born in 1952 in Cornwall-on-Hudson, New York. He graduated from West Point in 1974, and was commissioned as a second lieutenant in the U.S. Army. In 1983, Petraeus graduated first in his class from the U.S. Army Command General Staff College. Subsequently, he attended Princeton University's Woodrow Wilson school of Public and International Affairs, earning a Master of Public Administration in 1985, and a Ph.D. in 1987. His dissertation was titled "The American Military and the Lessons of Vietnam: A Study of Military Influence and the Use of Force in

General David Petraeus meets with U.S. Senator Robert Byrd (D-WV) in January 2007. Petraeus drew national attention when he testified before Congress in 2008. Some Republicans viewed Petraeus as a possible 2008 presidential candidate, and although that did not occur, he was appointed commander of International Security Assistance Forces in Afghanistan by President Barack Obama in 2010.

the Post-Vietnam Era”; it focused on the application of counterinsurgency in modern conflicts. He later used his expertise to oversee the rewriting of the U.S. Army’s *Counterinsurgency Field Manual*.

After earning his doctorate, Petraeus briefly taught at West Point; he then returned to active service. Notable assignments included membership in the North Atlantic Treaty Organization (NATO) Stabilization Forces in Bosnia, and serving as commander of the 101st Airborne Division in Baghdad, Iraq. In 2007, after a rapid series of promotions, he achieved the rank of general, and was selected as commander of the Multi-National Forces in Iraq. In October 2008, Petraeus became commander of U.S. Central Command, headquartered at MacDill Air Force Base in Tampa, Florida.

During the later years of the Iraq War, Petraeus became a national figure. In 2006, Petraeus was

part of a group of civilian and military officials who argued that the United States should cease its troop withdrawals and instead send more soldiers to Iraq to focus on population security and winning “hearts and minds”; this policy was dubbed the “surge.” In January 2007, President George W. Bush adopted the idea of the surge and announced that he was sending more than 20,000 additional soldiers to Iraq. By 2008, the surge had led to a marked reduction in violence in Iraq, and Petraeus’s subsequent testimony before Congress garnered him national attention and praise, with some Republicans suggesting him as a 2008 presidential candidate.

Petraeus continued to occupy a prominent role during the Obama administration. In 2010, the president appointed him commander of International Security Assistance Forces in Afghanistan. Subsequently, in 2011, Obama nominated him

to as director of the CIA. He retired from the military to accept this position, and in June, the Senate unanimously confirmed him. He served as director until his resignation in November 2012.

The Affair

Broadwell and Petraeus first met in April 2006, when Petraeus gave a speech at Harvard's Kennedy School of Government; Broadwell was enrolled in a Master's program there. Broadwell, who transferred to King's College to pursue her Ph.D., made Petraeus's leadership style the subject of her dissertation. She interviewed Petraeus through e-mail, and eventually traveled to Afghanistan to meet with him in person. Her unfinished dissertation became the basis for her best selling biography of Petraeus, titled *All In: The Education of General David Petraeus*. The book was coauthored by Vernon Loeb, and was published in 2012.

Like Petraeus, Broadwell, who was born in 1972 in North Dakota, was a graduate of West Point. Broadwell then received a Master's degree from the University of Denver, and served in the U.S. Army and U.S. Army Reserves. In August 2012, she achieved the rank of lieutenant colonel. The Army Reserves, however, later revoked this promotion when her extramarital affair came to light. Broadwell was married, and had two children.

According to news reports, the affair between Petraeus and Broadwell began sometime in late fall 2011, after Petraeus retired from the military and was confirmed as CIA director. The affair ended in mid-2012.

The Scandal

The roots of the scandal were in messages Broadwell anonymously sent to Jill Kelley, a wealthy resident of Tampa, who frequently hosted and attended parties for top military officials at MacDill Air Force Base. The e-mails contained details about Kelley and Petraeus's social activities, and warned Kelley to stay away from an unnamed man. In response, Kelley contacted a local FBI agent, and requested that he investigate the source of the e-mails.

Since the e-mails contained details about Petraeus's schedule that were not public knowledge, the Justice Department also became involved in a formal investigation into potential

security breaches. The investigators eventually traced the e-mails, sent from multiple accounts, to Broadwell. Subsequently, federal investigators also found that Broadwell was using the accounts to communicate with Petraeus. In an attempt to avoid an electronic record of their communication, Petraeus and Broadwell would use a Gmail account to compose messages, and then save them in the draft folder.

In late October 2012, both Broadwell and Petraeus admitted the affair to investigators. By early November, when it became clear that the story would become public, Petraeus decided to resign. On November 8, two days after Obama's re-election, Petraeus offered his resignation, which the president accepted the following day. The investigation is ongoing, and federal investigators have searched the homes of both Broadwell and Petraeus to discover if either possessed classified material. In March 2013, the Senate confirmed John O. Brennan to replace Petraeus as CIA director.

Pew Internet and American Life Project

The Pew Internet and American Life Project is a nonprofit, nonpartisan initiative that aims to collect and disseminate information on the social impact of the Internet in the United States. The Pew Internet and American Life Project is one of seven projects that are coordinated by the Pew

Research Center whose motto—"numbers, facts and trends shaping your world"—aptly summarizes its mission. The Pew Research Center describes itself as a "fact tank" because it places emphasis on generating data and facts on important issues affecting the United States and the world. The center does not offer policy recommendations or endorse any industry, organization, or individual. The umbrella organization, the Pew Charitable Trusts, was established in 1948, and provides the bulk of financial support for the Pew Research Center, yet it upholds the center's independence and neutrality.

The Pew Internet and American Life Project was established in 1999 with the help of a \$5.9 million, three-year grant by the Pew Charitable Trusts. The idea was conceived when Pew Charitable Trusts staff members recognized the need to generate reliable data on what people do online, and how their Internet use was affecting their lives. Because existing research at the time predominantly centered on the commercial role of the Internet, project creators decided to fill the gap by researching the wide social implications of this new medium, thus placing special emphasis on families, communities, education, health, politics, and news.

The Pew Internet and American Life Project became part of the Pew Research Center in 2004, when the Pew Charitable Trusts announced that it was consolidating all its research projects under one nonprofit subsidiary. The Pew Internet and American Life Project director is Harrison "Lee" Rainie, former managing editor of *U.S. News & World Report*. The offices of the Pew Internet and American Life Project are located in Washington, D.C., and the project currently employs a staff of nine research experts.

The first report, titled "Tracking Online Life," was published in May 2000, and examined the role of the Internet in Americans' everyday lives. Some of the early reports were based on surveys completed in the 1990s by Andrew Kohut, who is director of the Pew Research Center for the People and the Press and founder of the Princeton Survey Research Associates.

With time, the scope of the Pew Internet and American Life Project research expanded to include timely examinations of such emergent Internet issues as online piracy, blogging, online

banking, and cloud computing. Since its creation, the project has produced more than 350 reports over 30 different topics. The Pew Internet and American Life Project reports can be divided into three broad categories: activities and pursuits, demographics, and technology and media. Special emphasis is given to teens, health, and broadband adoption. The project also provides separate trend data on adults and teens, as well as infographics on key research topics. The project makes it clear that it does not take a position on policy issues related to the Internet.

The data collection methods of the Pew Internet and American Life Project are aligned with the rigorous research methods of the Pew Research Center, and are grounded in public opinion polling and social science research. The project's research reports are often regarded as an authoritative source among policymakers, scholars, journalists, and bloggers.

The project's Web site lists hundreds of media mentions by such prestigious news organizations as the *New York Times*, *Washington Post*, PBS, the Associated Press, and Reuters. In line with its research focus, the Pew Internet and American Life Project maintains an active Web presence, with regularly updated profiles on all major social networks. The project also makes available for free the full versions of its reports and its data sets on its Web site, but users need to follow its user policy guidelines.

Phishing, Political

Phishing is the act of enticing a person into revealing private information by masquerading as a trustworthy entity. Phishing can be used to steal any type of restricted information (e.g., money, hospital records), and can be accomplished through any communication technology (e.g., e-mail or voicemail), as well as in person. In the political realm, phishing refers to the theft of personal information by masquerading as a political entity, most commonly a politician running for office who requests donations from supporters. In this case, the victim gives money to the phisher, rather than to the politician. As a result, both the campaign donor and the legitimate politician who might have benefited from the donation are defrauded.

Political phishing can also refer to conning politicians and government officials into disclosing confidential information, such as national security intelligence and plans for political campaigns, which can then be used for terrorism, espionage, or sabotage. Studies show that phishing is prevalent in the United States and results in substantial monetary damages, although there are no such statistics currently available on political phishing in particular.

Several remedies have been proposed to reduce the impact of phishing attacks. These include both technical solutions (i.e., developing blacklists of phishing sites and removing them from the Internet, building better antispyware software) and user education programs on how to recognize fraudulent e-mails and Web sites. Both have shown effectiveness.

The term *phishing* is believed to be a word play on "fishing," because it refers to the baiting of individuals through illicit messages, with the initial letters standing in for "password-harvesting." The majority of phishing attacks are perpetrated over e-mail, with phishers pretending to be a bank or financial institution, and requesting users to login to their accounts in order to verify information or change their personal identification numbers (PINs).

The e-mail directs users to a fraudulent Web site, where their private information is captured and later used to steal money. Another common phishing technique is installing malicious software (malware) on users' computers when they simply click on a fraudulent Web site or open an infected e-mail attachment. The malware then steals private information from users' computers through key logging or downloading Internet browsing caches. The most successful type of phishing, known as "spear-phishing" because of its highly targeted nature, involves including some personal information, such as names, dates of birth, and the last four digits of credit card numbers, in e-mails sent to potential victims. The users interpret this information as a sign of e-mail credibility, when in fact it is mined from the Internet by the phishers, or is simply made up.

Political Phishing

Campaign donations are a particularly ripe target for e-mail phishing. First, politicians have exempted their campaign donation solicitation e-mails from the CAN-SPAM Act, which prohibits the promotion of commercial products and services through unsolicited e-mail. As a result, the public is less suspicious of receiving campaign donation requests from politicians via e-mail. Second, political domain names tend to fluctuate, which makes the public less able to distinguish between real and fake ones. For instance, President Barack Obama may use barack4president.com, obama12.com, or barackobama.com. All of these Web sites appear legitimate, yet some of them may be phishing scams. By contrast, financial institutions maintain strict consistency in their domain names precisely in order to avoid confusion between their real Web sites and a phishing impersonator. Third, it is relatively easy to mine for information about political affiliation in

order to create personalized spear-phishing campaigns. This information can be found on social network sites or on records of individuals' prior campaign contributions, which are publicly available online, as required by law. Finally, political phishing may be less detectable than other types of phishing. Provided that phishers do not steal more money than the intended campaign contribution, the victims may not even realize that they have been defrauded. Political phishing Web sites may then be less likely to be blacklisted and taken off the Internet.

To combat political phishing, politicians have adopted two noteworthy tactics. One is brand consolidation, or funneling campaign donations for multiple politicians through a centralized donation Web site, the Democratic ActBlue and the Republican RightRoots. The other is enabling donations through users' existing accounts with PayPal and Google. These strategies help avoid confusion between candidates' domain names, and forgo the necessity of inputting financial information for every donation, thus reducing contributors' susceptibility to phishing scams.

Picasa

The proliferation of broadband Internet, digital cameras, and smartphones has made photo sharing a popular communication practice. Picasa is Google's Web- and desktop-based application for sharing digital photographs. Created by Lifescape, initially Picasa was a software package for organizing and storing photos for Microsoft Windows. In 2004, Google acquired Picasa from Lifescape, released it free of charge, and developed it for Windows, Mac operating system (iOS), and Linux. Picasa is a part of Google's attempt to establish an entire ecosystem of software services that include social networking, e-mailing, photo sharing, and file or document sharing. The role of Picasa in this all-inclusive system is to act as a hub for the storage and circulation of photos. Any Google service that can carry image-based content will automatically sync with the user's Picasa account. For example, files stored on Picasa can be uploaded to another Google service, such as Blogger, while any files uploaded to Blogger will automatically appear on the user's Picasa account, and can then be recirculated to another service such as the social network Orkut.

In addition to making the software available across a range of operating systems, Google developed Picasa Web, the online portal of Picasa. Most users use Picasa Web to upload, store, and share their photos in photo albums. Like many other forms of social media, Picasa's organizational structure works with tags, which are searchable by the general public. Users can disseminate the content of their photos in several ways. For example, customized user-generated tags let Picasa users browse through their photo albums or other people's photo collections in an associational way. Users can also contribute to threaded discussions regarding photo content by making comments and sharing photos on their other Google accounts, thereby generating traffic. This networking functionality allows users to partake in a form of asynchronous social interaction around photos in the online domain. Similar to Flickr, the threaded discussion acts as an archive of social interaction that can be added to at various times.

Image-centric social media developments such as Picasa are changing both online and offline

viewing practices. Picasa's search functionalities facilitate the organization and display of photos in that they can recognize all image files on the user's hard drive. From there, one can upload all the photos, or a selection, and organize them into folders to showcase for their family and friends. Picasa also provides an offline photo sharing and viewing platform with a slideshow. Additionally, movies can be made with Picasa's Movie Maker editing tool, shared across other Google services, and most importantly, uploaded directly to YouTube. This cross-platform flexibility and range of interlinked functions means that a variety of users—ordinary citizens, professional photographers, photo agencies, and magazines—all take advantage of Picasa.

One of the benefits of Picasa is its potential for those interested in photojournalism as a part of citizen-driven social media. With Picasa, users can attach photos to their e-mail, or immediately upload them to social media sites like Twitter or Facebook if they have a network connection. Newspapers often source photos of international events downloaded from Picasa when they want to showcase "citizen media." Potentially useful during times of political protest or civil unrest, Picasa developers have created plug-ins that allow users to directly post photographs to non-Google-owned networks such as Facebook and Twitter. However, Picasa's plug-ins are not as well integrated with mobile phone services, limiting its use as a form of citizen-based media-making during a crisis. Crucially, (at present) Picasa has no free, proprietary iPhone app, and its Android equivalent is a paid service, whereas other major social networking apps for mobile devices feature free mobile services for photo sharing, such as Facebook's Instagram.

Those engaged in citizen media-making as of late 2012 tended to rely on social networks such as Twitter and Facebook for instantaneously photo-publishing to a dedicated group of followers. While Google's ubiquity is persistent, Picasa's future remains uncertain. According to the most recent data, its use, along with Flickr, is stagnating because of its poor mobile integration. The ubiquity of 3G mobile phones is a key factor in social media pervasiveness. Without an easy way to upload and share photos, citizens are less likely to use this application for real-time sharing. Social

media is about accessibility and speed. Picasa's structure is more conducive to long-term storing and archiving of photos.

Piccadilly Riots, London

August 6 to August 11, 2011, represented a time of widespread rioting and civil unrest throughout London and the surrounding area. What began as a peaceful protest against the rising poverty and unemployment in areas of north London was quickly transformed into a violent situation when Mark Duggan, a young man and father of four, was killed in Tottenham. During these five nights of unrest, there were over 4,000 arrests and 5,112 individual riot-related crimes. Slightly more than half of the crimes were committed against commercial shops. This was not an isolated event—on several occasions earlier in 2011, groups of students and youths had rioted throughout London. The August 2011 riots were unique because of the use of social media.

Reactions to Social Media Use During Riots

This riot in London represented one of the first large-scale uses of many types of social media

that functioned to help rioters organize, gain recognition (e.g., posting photos of people rioting), and spread information in novel ways. People used Twitter and Facebook to publicly post information that was retweeted and broadly shared, and they also used private messaging networks through services like BlackBerry Messenger. By using social media, ordinary people gained the power to observe and participate in diverse digital conversations—practices previously reserved for governments, police departments, and organizations with access to private networks. This extensive use of social media prompted a new type of blame game. Social media became a player, along with the actions of individuals, and it was easy to blame these new communication tools for fueling and even causing the riots.

One of the more controversial reactions to the prolific use of social media during these riots was that of David Cameron, the prime minister. Quite early during the riots, Cameron made broad claims that were interpreted by the media and citizens as an intent to limit free speech. Cameron talked of banning the use of social networking sites like Twitter and Facebook, in addition

to requiring the media to turn over any unused riot footage. Cameron also had the home secretary, Teresa May, meet with representatives from Facebook, Twitter, and Research In Motion (the manufacturer of the BlackBerry mobile device). Government officials attempted to pressure the companies that were providing these new social communication tools to shut down networks, monitor conversations, and limit the type of conversations. The discussion of these bans on social media use during times of unrest continued for a month following the riots, but were later dropped.

These riots also represented one of the more public accounts of how police reacted to the use of social media, and in particular, the use of private networks through BlackBerry Messenger, to help rioters organize. Police officers have protocols concerning when and how they intervene during times of unrest. Yet, with claims of racism and prejudice in the air, police found themselves in a pivotal position: do little and watch the destruction abound, or act with force and risk criticism. The combination of this uncertain time period and the explosion of communication through

Firefighters attempt to extinguish a large fire at a Party Superstore on Lavender Hill, Clapham Junction, August 8, 2011, during riots. The majority of crimes committed included vehicles being set on fire and commercial shops ransacked, looted, and set on fire during the five nights of unrest in north London.

social media forced the police to deal with new forms of organization and a crowd temperament that required faster investigations and reactions than in past civil violence situations. As a result, individuals were arrested for statements posted on social media platforms if the content was believed to be capable of inciting violence. A report generated by the United Kingdom (UK) government made formal recommendations concerning the riots, and suggested that not only the Metropolitan Police Department, but all police organizations maintain a regular presence on Twitter.

The Plurality of Social Media

The reactions and realizations resulting from the use of social media during the London riots mimic those found in other types of organizational crises and emergencies. While much of the rhetoric surrounding limiting social media use during the riots was couched as a limit on free speech, in reality, controlling messages and communication channels is likely to be logistically impossible. While networks can be shut down in a given area, so many different social media platforms exist that getting total cooperation when time is limited is highly unlikely. This shift in the speed and transparency of communication has forced many organizations to rethink their role in crafting and controlling messages. The entire field of public relations now encourages organizations to embrace a new way to approach communication—one where joint messages are created and the social aspects of these new media are harnessed.

These riots also demonstrated the power that social media has as a conduit for groups of like-minded individuals to organize and perpetuate activities like riots. When people can simply touch a button and share information with their entire contact list, even the metaphor of “spreading like wildfire” seems too slow of a description. In a short period of time, the Web of influence can experience extreme distribution.

However, this type of rapid self-organization does not mean one cannot model, predict, and learn from these crowd behaviors. Several studies have used the London riot data to generate predictive models to help justify the number of police needed and approaches to take if these situations occur again.

Differences in Social Media Use

After the riots, *The Guardian* partnered with the London School of Economics to conduct a number of studies that they titled Reading the Riots. Extensive interviews were conducted with a wide range of stakeholders involved in the riots. This included rioters, victims, police, and court officials, and the study covered a wide geography. In addition, 2.5 million tweets were analyzed, and researchers found that Twitter played a big role in clean up after the riot, but only a small role in actual riot conversation. The hashtag #riotcleanup was posted by more than 12,000 people and the messages were retweeted more than 31,000 times. The messages on Twitter helped people, find others who were also interested in rebuilding their community. While the vast majority of the reports surrounding the use of social media during the riot focused on their destructive impact, it is hopeful to have documentation that there were also many people organizing clean-up efforts, collecting donations to help victims, and combining efforts to rebuild businesses.

BlackBerry Messenger (BBM) was actually the dominate communication channel used by the active rioters. This may seem odd because BlackBerrys are often considered the tools of business communicators. Yet, in London at the time of the riots, BlackBerrys were fairly inexpensive because mobile users could pay for services by the month. Once that low fee was paid, BBM messages could be sent to a user’s entire contact list very quickly with no extra fees. These mobile devices became very popular with young and poorer people in London. Combine the low cost of service with the fact that BlackBerry operated an encrypted private service that could not be monitored by the police, and it is not surprising that this tool became the dominant device used to spread riot information.

One major lesson that should be learned from discussions of the role of social media during riots is that social media perform different functions and lumping them all together is inaccurate. An industry social media researcher, danah boyd, has studied social network sites and how they function differently than social tools that facilitate private communication and information sharing. In the UK riots, BBM was the chosen tool of rioters because most of them did not want to post information publicly and risk arrest. The rioters and

bystanders who chose to use more public media like Twitter and Facebook likely did so knowing that there was a risk involved. This risk was outweighed by the publicity they garnered for themselves and their causes. When the content shifted from illegal activities to organizing for cleanup and rebuilding, the more public social media emerged as a dominant communication channel.

This multiday UK riot will be remembered as one of the early crises where a mix of communication technologies, including social media, was used to perpetuate, publicize, and clean-up from an emergency. The resulting mixed messages and blame on technology highlight the complex information and communication technologies that will continue to morph into new forms and communication practices.

Pinterest

Pinterest is a social networking site through which users share their favorite images of interests, hobbies, and activities. It is estimated to be the fastest growing and third-largest social media site, behind only Facebook and Twitter, with over 48 million users as of April 2013. According to the Pew Internet and American Life Project, 12 percent of online adults and nearly a fifth of online women (19 percent) use Pinterest.

The user space is the equivalent of virtual bulletin boards, within which one can pin or collate images from across the Internet. Users can have multiple boards for different topics or themes. Postings are called "pins," and users can either use Pinterest buttons embedded by owners in their Web sites, or a "Pin It" button in their Web browser to create a pin. Each pin includes a caption, a short descriptions of the image, and links back to the site from which it originated. Other users can comment on pins and repin items to their boards. Users can easily post their pins to their Facebook and Twitter accounts.

Uses

Pinterest is only limited by the imaginations of users. Also, while the original use of Pinterest focused on visually beautiful images, it did not take long for companies and corporations to add it to their social media campaigns to advertise products and services. Both individuals and organizations have adopted the site to advocate for their social causes and advance their messages through social marketing.

For example, the United Nations Children's Fund (UNICEF) created a Pinterest board called "Really Want These" (pinterest.com/AmiMusa/really-want-these), which helps users view the world through the eyes of a fictional girl from Sierra Leone. The items portrayed are the basic necessities of everyday life such as grain, water, and soap. Following Hurricane Sandy, the ad agency of Y & R Midwest created a board "Helpin," which allowed families to create boards identifying the items they needed. Purchases were made through Amazon.com and shipped directly to the family's home. Petfinder.com posts pictures of adoptable pets to Pinterest to help find homes for animals. Pinterest also offers educational opportunities for

curating collections of course resources and the development of class projects.

Web site owners have become aware of the importance of the quality of their images to increasing their visibility on Pinterest. Recently, Pinterest added the ability for business users to list a link to their Web sites, which appears at the top of their Pinterest page, right under their account name and description.

Users can now click and go directly to the original Web site. Along with this convenient and expedited Web access, Pinterest also introduced Web-based analytics to help Web site owners track and analyze how Pinterest users utilize their Web sites. Site owners can track the number of pinners and pins used, as well as the number of pins and repins from the original first-generation users. They can also track total impressions and reach on the network, as well as referral traffic, both in clicks and unique visitors via data sent back to their sites.

Pinterest and Politics

Social media use has grown in recent years as a tool for political action and civic engagement. According to the Pew Research Project on American Life and the Internet, 39 percent of all American adults participated in some sort of political activity on a social-networking site during the 2012 campaign. And while this study specifically looked at Facebook and Twitter users, several of the political activities they described could also be performed on Pinterest, including: posting links to political stories or articles, following a political candidate or other political figure, encouraging others to vote, voicing one's opinion on political candidates or issues, encouraging others to take action on political issues of importance to the poster, or belonging to a group on a social networking site involved in advancing a political or social issue.

Individuals can use Pinterest to advance their political views, just as fans might create a board for a celebrity. Such pages do not necessarily have the approval of the candidates they support. In addition, other users may create anti-candidate or anti-policy boards that portray negative views of individuals, political parties, or programs. Political cartoons and satirical material are easily pinned and repinned. If one types in "politics" in

Pinterest page of Ann Romney, wife of 2012 presidential candidate Mitt Romney, still had nearly 17,000 followers at the end of 2013. The page contains sections such as "Books Worth Reading," "Things I Love," and "Inspiration."

the Pinterest search engine, hundreds of pins and boards show up. Interestingly, a review of major newspaper Pinterest boards shows that they focus primarily on beauty, fashion, food, entertainment, sports, and so on, with little emphasis on politics, while the TV news networks include political boards and top news stories boards that may include political articles. Individuals can easily repin these to their boards.

As might be expected, political candidates, campaigns, and parties have embraced Pinterest as part of their social media campaigns. "Politics" does not exist as a topic on the drop-down menu of categories in the Pinterest menu. A little research leads to the discovery of many political boards and pinners. President Obama is a social media savvy politician with an official page run by the Obama for America 2012 presidential campaign (pinterest.com/barackobama). Both the White House (pinterest.com/whitehouse) and the United Kingdom's Prime Minister (pinterest.com/number10gov), among others, have Pinterest boards to share news and photos with their constituents. Governmental units such as the U.S. Department of State (pinterest.com/usdos), the CDC's National Prevention Information Network (NPIN) (pinterest.com/cdcnpin),

and the U.S. Department of Health and Human Services (pinterest.com/hhs.gov) maintain Pinterest presences. A search for “senator” or “representative” located numerous pages for state and federal Congress members. Searches for both the Republican and Democratic parties found sites for state and local committees. Both potential First Ladies Michelle Obama and Ann Romney used Pinterest to create a sense of “homey connection” with voters during the 2012 presidential campaign.

Conclusion

Pinterest is a relatively new social media networking site, only opening by invitation for beta testing in 2010, yet it already has a significant following of individual and organizational users. One can expect that it will continue to be used for political as well as educational and recreational activities. Its multiplatform applications (for smartphones, tablets, and computers) allow individuals to easily curate images and content from across the Internet about candidates and political and social issues.

Pioneers in Social Media and Politics

Pioneers in social media are individuals, groups, and institutions that offer innovative leadership in finding more effective ways of providing technological and human interchanges and connection. Traditional systems of communication that depend on unidirectional flows and top-down models have been revolutionized by modern social media, which have democratized the process by empowering individuals, groups, and hitherto marginalized populations into becoming active players in governance and participatory politics.

Debates on the exact meaning of social media, the pioneers of the phenomenon, and its impact on politics rage throughout the world. Hence, a broader view, tracing the highlights of the revolution without having to attribute exclusive credit to particular individuals or single events, is imperative. Social media in its contemporary form emerges from the confluence of advances in technology and movements for pluralism, expanded public space, and connections among citizens. Movements for social change and networks joined with revolutions in the technologies of communication and information to produce social media as a vehicle for facilitating political change.

History

In tracing the pioneers of social media, the multiplicity of human agencies as well as institutions, policies, and movements in collectively shaping its trajectories of change cannot be overemphasized. Visionaries, leaders, scientists, artists, technology experts, entrepreneurs, and individuals committed to creating new worlds have all contributed.

Framed in historical context, the advance of science and technology is described by Freeman J. Dyson in his book, *The Sun, the Genome and the Internet: Tools of Scientific Revolutions to Under-score the Joint Human Heritages of the Brain and*

Hands as the Basis of Civilizations. From ancient times to the industrial and contemporary revolutions, he notes that abstract thinkers have had to forge relations with practical inventors and craftspersons. This practice has continued today, as centers of scientific research are ensconced among industry, as seen now with involvement by, for example, Stanford, Harvard, MIT, Princeton, and Rutgers in technology centers such as Silicon Valley and Route 128 in Boston, which also thrive as interdependent environments. Other analysts corroborate this observation by showing the contributions of public policies to providing semi-autonomous research institutions such as the U.S. Advanced Research Projects Agency (ARPA) and its successor ARPANET, and the European laboratory for particle physics, CERN. All are complemented by the imaginative efforts of independent technology experts and hobbyists, as well as business and social entrepreneurs from such organizations as IBM, Bell Labs, the National Science Foundation, and RAND.

Blaise Pascal's calculator in 1642 introduced the modern era of automation. Gottfried Leibnitz and Isaac Newton's work, which improved on Pascal's calculator, is believed to have laid the groundwork for Charles Babbage's further refinement of the concepts for a mechanical computer in the 1820s. Ada Lovelace's great contribution in building on Babbage's analytical engine using the first algorithm earned her the standing of the "world's first computer programmer." The computer has been described as a complex piece of machinery comprising multiple parts, often considered as separate inventions credited to different individuals. The list of inventors ranges from Konrad Zuse and John Atanasoff to Howard Aiken and Grace Hopper. Institutions involved in its development include many universities, General Electric, the Bank of America, IBM, and Microsoft, among others.

Innovators as diverse as governments, investors, hobbyists, consultants, political and civic leaders, journalists, visionaries, and tech wizards have all been associated with the rise and development of the new media made possible by computers. They include the founders of Apple, Steven P. Jobs and Stephen G. Wozniak; Internet service providers such as AOL and Yahoo!; and Microsoft developer Bill Gates. Other notable

social media pioneers include Facebook developers Mark Zuckerberg, Eduardo Severin, Dustin Moskovitz, and Chris Hughes; Twitter heavyweights Jack Dorsey, Noah Glass, Florian Weber, Evan Williams, and Biz Stone; Google leadership Larry Page and Sergey Brin (with Andy Bechtolsheim as a visionary early funder); and YouTube inventors Steven Chen, Chad Hurley, and Jawed Karim.

Like the computer, the Internet is also viewed as a byproduct of multiple innovators with competing narratives. Credit is due to government, business, and high-tech entrepreneurs. Responding to public debates attributing the Internet to government guidance and Al Gore's claim of shepherding it through Congress, Bob Kahn and Vincent Cerf, often called the fathers of the Internet, noted his support for the growth and development of the Internet for an extended period beginning in the 1970s in a paper titled "Al Gore and the Internet."

Social Media and Politics

The development of social media has brought about greater grassroots engagement and the democratization of access to information, especially through its reduction of the cost of communication. In *The Creation of the Media-Political Origins of Modern Communications*, Paul Starr argues that the modern media, symbolized by the leading role that the U.S. system has played in the world, is a byproduct of the political structures and ethos that have created environments of pluralism and decentralized governance. Social media, with its inclusion of a broad array of actors from scientists, technical experts, visionaries, public servants, ordinary citizens, community groups, and grassroots institutions, set the stage for the empowerment of individuals or marginal groups to establish power centers.

In the organizational column are entities such as ARPA, which paved the way with the first e-mail message in 1971, and CompuServe, which was at the forefront with its dial-up technology and service, enabling members to participate in common forums. The bulletin board system (BBS) provided online meeting places for users to share files and messages, while America Online (AOL), which has been described as "the Internet before the Internet," blazed a trail with innovative

platforms of interactive information paradigms. Pioneering transformations in integrating the social and political followed from companies such as Friendster, LinkedIn, Myspace, Facebook, and Twitter.

As mentioned previously, individual pioneers playing leading roles in mass movements in technology and social change include Tim Berners-Lee of CERN, who offered the technical basis for the operation of the World Wide Web; Steve Case and Kim Kimsey, cofounders of AOL; Tom Anderson and Chris DeWolfe, cofounders of Myspace; Steve Chen, Jawed Kim, and Chad Hurley, cofounders of YouTube; and Larry Page and Sergey Brin, cofounders of Google. Jack Dorsey's Twitter has also demonstrated its extensive impact on social networking and politics with its growth in membership and geographic spread.

However, Mark Zuckerberg's Facebook has had the most profound impact on politics and society, as David Kirkpatrick emphasizes in *The Facebook Effect*, which illustrates its influence by its operation in 75 languages and its transformative impact on global politics and society, although many political analysts feel that Twitter is also emerging as a political game-changer, particularly in light of its conspicuous role in the U.S. 2012 presidential election.

Because of the fusion of technological, social, and political movements in driving transformations, distinct boundaries between pioneers in particular areas cannot be drawn. On the foundations laid to revolutionize communication from the traditional top-down and linear paradigms, pioneers in politics have fully utilized social media in conveying their visions and ideas, mobilizing followers and establishing alternate organizations. As noted in the preceding discussions relating to different fields of endeavor, whole movements and group efforts have gone into the pioneering work of politics.

The building blocks of social media and politics, including the creation of relationships, direct transmission of information, and establishment of supportive networks, are believed to have been practiced long before the current terminology limited it to the modern technological revolution. As such, a large number of visionary leaders, activists, and change agents are placed in the category. Some observers point to leaders

such as Franklin Roosevelt and John F. Kennedy as pioneers. Others even point to Jerry Garcia as the innovator who operationalized the ethos of social media.

The difficulty of tracing visionaries and participants in pioneering social media and politics is illustrated by countless individuals' overlapping contributions and competing claims to ownership of particular technological innovations, sociopolitical ideas, or even terminologies. Regarding a debate over who first coined the term *social media*, Ted Leonsis responded to a contested narrative about Tina Sharkey's claim of the term's authorship by pointing out that the concept developed from his and Steve Case's attempt to craft an instant messenger that fused technology and communications with social networking. Digital innovators, political leaders, bloggers, social activists, and forerunners of change all contributed to the transformative phenomenon.

In the United States, a leader in the revolution, pioneers representing different aspects of the process include Evan Williams of Blogger, Jim Bumgardner's The Palace, Adrian Scott's Raze, as well as Rick Sanchez with his use of social media to bolster news, as well as Elizabeth Lindsey, Jude Owner, Maddy Harland, and scores of visionaries as founders emphasizing varied dimensions. Social media pioneers in politics such as Joan Blades and Wes Boyd, with MoveOn.org, introduced the creative power of social media to mobilize grassroots involvement in national politics.

Pioneers in Politics

Globally, pioneers in politics mirrored the American experience with social media as the new alternate mode of communication enabled movements, parties, and individuals to rise or fall from critiques raised by the new platform. Political movements organized and facilitated by social media led to the ouster of leaders or governing parties in the Philippines, Spain, and Moldavia. Egyptian and Tunisian uprisings largely spurred by the media resulted in attempts to curtail this freedom, and the fall of oppressive leaders. Attempts at suppression have occurred in Iran, Belarus, Zimbabwe, Angola, Russia, and China. Occupy Wall Street protests in such cities as New

York, Oakland, Quebec, Barcelona, and Chicago challenged the status quo of finance and politics.

To put human faces on the pioneers, mention could again be made of the prominent exemplars whose workings on politics and organization are considered transformative by the social media of the world. The United States is credited with introducing social media into high politics. Other figures like Governor Howard Dean of Vermont laid the groundwork of digital activism for political causes and office. However, Barack Obama is rightly celebrated as the political figure who pioneered such methods and changed political communication, fundraising, and mobilization worldwide.

Candidates to congresses and parliaments, governors, and leaders in public institutions now engage their constituencies through digital media. A good example of the power of the Facebook effect has been Oscar Morales, a Colombian citizen who confronted the guerrilla politics of kidnapping. His mobilization of demonstrations throughout world's cities using Facebook resulted in the release of a hostage.

In Russia, Aleksei Navalny, an anticorruption blogger, is acknowledged as a maverick who sparked an opposition movement through a Russian equivalent of Facebook, Vkontakte. Chinese dissident artist Ai Weiwei is recognized as a voice of alternate politics mediated by social media. Wael Ghonim, who spearheaded the mobilization of followers in Egypt through Facebook and Twitter, is honored as a pioneer in the region. Ory Okolloh's online campaign on Ushahidi moderated the brutality of political violence in Kenya. Kim Ou-Joon and his colleagues, with their satirical weekly podcast called *Neneuen Ggomsuda*, also pioneered a political paradigm of multilateral engagement of public discourses with academic and political constituencies.

The list of innovators and participants linking social media and political pioneers with momentous events and transformed realities is long. Nevertheless, the salience of the revolution and its huge number of actors spanning geographic, cultural, and ideological boundaries cannot be exaggerated.

Platform

Microblogging sites such as Twitter, video-sharing sites such as YouTube, and social-network sites such as Facebook are social media platforms. The metaphor of a platform refers to a horizontal structure raised above a particular situation; for example, a stage for public speakers. Translated to the digital realm, the platform renders social media sites accessible for ordinary people to voice themselves. This understanding of a platform as an empty vessel of communication rests on the combined notions of equal opportunity and technological neutrality. Framing social media sites as neutral platforms, however, tends to conceal a key tension in their relationships to politics. The public use of social media platforms for political discourse is structured by the commercial imperatives behind these sites.

Social media platforms have become strategic political fields, as citizens across the world use them to gather together, express their opinions, protest injustices, and mobilize around civic initiatives. Politicians also use them as platforms for campaigning and public communication. The

large user base of platforms like Facebook, YouTube, and Twitter are the product of not only their usefulness in communication practices, but also of the profit incentives guiding their provision of a “free” communication infrastructure. The drive to profit from user data and behavior shapes Web site architecture and policies primarily in the service of private interests, rather than public spheres.

The central function of the term *platform* in this context is to elide the power differential between commercial actors and “ordinary” users. At the same time, however, the political activity of ordinary people using social media platforms is significant. Especially in massive political mobilizations such as the Arab Spring of 2011 or the Québec student protests of 2012, social media platforms played a central role in facilitating physical demonstrations that in many cases led to political change. As ordinary people increasingly circulate their views on the Web, for the first time in history, the breadth and scope of citizen perspectives and debates becomes archived and accessible.

However, as Tarleton Gillespie argues, platforms are not neutral. The promise of the platform as a level playing field for social participation obscures asymmetrical power dynamics between users and corporate powers that exploit and appropriate user participation. Advertising is the central mechanism through which social media platforms exert control over users. Personal information about users is collected in exchange for their access to commercial social media sites, in accordance with the terms and conditions agreed to upon signing up. Further, user behaviors online, such as page visits, clicks, and search terms, are also monitored and compiled as part of “behavioral advertising” models that seek to predict future consumer behavior based on the patterns of individual users.

Ultimately, the advertising imperative that underlies social media platforms effectively limits the scope of users’ online action by consolidating Web content into the interface of a particular social media platform. Facebook, for example, compiles various online content in its newsfeed, and at the same time, Facebook’s trademark “like” button is ubiquitous across the Web. The corporate monopolies of Facebook,

YouTube, and Twitter are leading to an increasing enclosure of users’ radius of online action. Instead of an open and accessible network, the Web is increasingly fenced off in proprietary walled gardens.

Thanks to the apparent equality and neutrality of a platform, this transformation and its attendant power dynamic tends to go unnoticed in everyday social media use. Most users remain unaware of how their actions and personal information generates value for platform owners. The political consequence of this is a widespread penetration of surveillance practices into the very architecture of social media platforms. While this surveillance is ostensibly a function of the platforms’ advertising models, it can also be used for political ends, such as in the aftermath of the Arab Spring, in which particular organizers were identified and targeted by repressive governments through their social media activities.

On the surface, social media platforms seem to provide an equal opportunity for all users to participate in public debate over a neutral communications infrastructure. Yet, the commercial motives behind sites like Facebook, YouTube, and Twitter seriously undermine the political promise of platforms in rendering users into commodities through what are effectively practices of online surveillance. The consequence of having commercially owned public spaces can be seen especially in politically turbulent situations, when corporate control over the means of communication tends to side with powerful private and authoritarian interests, as opposed to the public interest. In this way, platforms are not neutral; they structure and regulate political discourse and freedom of expression.

Podcasts

Podcasts are audio recordings that are disseminated via the Internet through a sound file. According to the latest Pew Research Center’s 2012 State of the News Media report, there are approximately 91,000 podcasts in existence and 25 percent of Americans reported listening to podcasts in 2011.

Podcasting began as an offshoot of blogging, when technology evolved to a point that it became possible to embed audio files into a blog post and disseminate them through the same channels as a blog. The term *podcast* was developed as a derivative of Apple Corporation’s iPod, an audio device that facilitates digital downloads and playback of audio files. The earliest appearances of the word in the lexicon date back to 2004; however, its adoption was quite rapid, as the *New Oxford American Dictionary* named “podcast” the word of the year for 2005. The term *podcast* is a bit of a misnomer because it infers that podcasts are only available for consumption via an iPod device, when in reality, they can be consumed via any computer if the proper software is downloaded. The podcasts are usually produced as an MP3 file for convenience because most players can accommodate that file type. Podcasts can be produced quickly and easily, and disseminated through a variety of social media channels. There are millions of podcast episodes in existence across a wide variety of genres, from education to sports, science to news, and politics. Listeners interested in a particular podcast series can also subscribe via an really simple syndication (RSS) feed, so that each new episode will automatically

download on the user’s device, instead of the user having to search for it on the Web. A variation of the podcast is the video podcast or “vodcast.” This is similar in concept to the podcast, but adds a visual element.

Attributes and Drawbacks

Podcasts offer the user the benefit of convenience and portability. They can be listened to during a commute to work or during an evening run, whenever and wherever is convenient for the listener. Improvements in technology even allow an amateur to produce a podcast that sounds as good as something a professional might create. However, this does not mean that every podcast is created equal. Without planning and attention to details such as acoustics, vocal quality, ambient noise, and good content, a podcast will fail. To be successful, podcasts should be relevant, on topic, and thoughtful.

It is important to recognize that almost anyone can produce a podcast and claim to be an expert on a topic. Podcasts are often not put through the same sort of editing or fact checking as would a piece produced by a media company. As a result, finding podcasts that are worth the time invested to listen to them is a challenge. If a podcast is embedded within a blog, there is often an opportunity to preview the content through an episode guide or synopsis so that the listener can evaluate the creator’s credentials and credibility and determine whether or not it is worth the time to listen. Podcasts are also one sided. They do not allow the listener to engage with the speaker as they might during a live broadcast. However, if the podcast is embedded within another medium like a blog, the author can use the comments feature in the blog to allow for interaction with the listeners.

Access to technology should also be considered with regard to the appropriate use of podcasts. Though it may seem otherwise, not everyone has Internet access. As a result, only a fragment of the population may be able to benefit from a podcast.

Podcasts and Politics

Podcasts have been used by a number of different political entities. Both major political parties and individual politicians have podcasts. At last count, there were over 250 different podcasts listed under the “News and Politics” category heading

on iTunes, Apple's library of downloadable podcasts. *The New Yorker* magazine, for example, produces the *Political Scene Podcast*, hosted by the magazine's executive editor, Washington correspondent, and others. The podcast discusses the previous week's White House activity. As private individuals can produce a podcast almost as easily as *The New Yorker*, it is now easier than ever for interested parties to contribute their voices to political discourse.

images, or videos that are shared from other media outlets. Coupled with the rise of partisan news channels, talk radio, and Web sites, there is a substantial amount of information that is presented in a way that confirms the views of its consumers, often offering only a token of dissent or none at all, which can be posted to a person's social networking pages and shared with their social networks.

This in turn allows these polarized versions of news stories to "go viral" and quickly circulate among these political communities. The effects of this polarization are debatable, and the extent to which social media increases polarization is likewise contentious. However, there is a substantial discourse surrounding political uses of social media, and their impacts on political polarization and this discourse seems likely to be influential for the foreseeable future.

Pro-Polarizing Effects

Much of the political discourse on social media tends to reinforce and accelerate the processes of political polarization. This is because social media users tend to subscribe to news from sources that share their ideological perspectives, and that are unlikely to challenge their views in any significant way. The sheer abundance of choice in this politically tailored media can even give the impression that one is exposed to a multitude of views, which is supposedly essential for the effective running of democratic governments.

However, the fact that people can see an enormous number of commentators and reporters echoing the same views and purported facts means that this impression is not only likely to be in error, it is also highly probable that their politically polarized views are reinforced by the sense that most people agree with this view. In other words, this self-selection of media is compounded via social media to create false impressions of majority belief and the unquestionable rationality and truth of one's political preferences. Genuine shock at election results that contradict one's expectations can result. Although this surely existed before the rise of social media, the potential problem for democracies is that this shock could be translated into questioning the validity of the results and the political process itself, which undermines the ultimate legitimacy of the

Polarization, Political

Political polarization is a process by which political opinions in a given population diverge toward extremes, generally along party lines. This process leads to a reduction in dialogue between people of different political views, and to a decreased chance of political compromise between them. Social media can be seen as both a causal factor in this process and a force that is shaped by it. The content of social media is often not original to that platform, but instead consists of articles,

government and makes it more difficult for leaders to actually govern.

Twitter is one of the most popular social media platforms in the world, boasting roughly 200 million regular users. Its popularity is partly because of its constraints on the number of characters allowed in each tweet, and the ease with which people can share a link to a longer article, site, or media clip via the platform. Political interaction with this social media platform occurs in at least three distinct ways. People can subscribe to Twitter feeds from political people and organizations, making it a fast way of getting bite-sized political messages from trusted sources. Alternatively, people can post political thoughts and links on their Twitter feeds, meaning that their ideas are shared with those following them. Even more popular is the practice of retweeting, which means simply forwarding existing political tweets on ones' feed, again creating the potential for a viral dynamic to emerge on a political issue.

Unlike other social media platforms, which often focus on relationships, the brevity of Twitter lends itself to use for quickly distributing brief thoughts that do not necessarily create much of a relational dynamic between users. Furthermore, the hashtag system, which allows Twitter users to identify relevant topics for their tweet, and which often have millions of potential followers, means that politically minded users can subscribe to specific party, issue, and candidate hashtags that conform to their views. As such, people are more likely to subscribe to Twitter feeds that correspond to their political views, and to have followers who are relatively politically homogeneous.

Social media interaction via YouTube videos tends to be highly impersonal. People may be sharing clips with others they know, but viewers are unlikely to have personal connections to those in the clip or those producing them. This means that comments sections below the clips can be notoriously vicious. These may range from disagreement with issues, to disparaging remarks about the content, to personal attacks on other commenters. Clearly, these factors mean that there is a low political trust factor, low personal interaction factor, and high risk of polarizing effects. The sorting of YouTube content into customized channels from already polarized partisan

news and political sources further exacerbates these effects.

Polarization can also occur via mashups of clips to make a larger partisan point about how "wrong" the other political side is on a given issue, or to mock candidates or positions. It can also occur via "gotcha" moments where candidates are exposed making significant gaffes or offensive remarks, often without the awareness that they are being recorded. These clips can then be reposted to other social networking platforms like Twitter and Facebook, and then used as a sort of opposition viral information effort to rally the politically like-minded around a given candidate or cause.

One of the other key social media sites is Facebook, which boasts regular user numbers of over 1 billion people. This makes it potentially one of the most important political tools in the world. Consequently, a great deal of effort has been spent by politicians and other political actors in democratic regimes in creating a meaningful presence on the site. As with other social media platforms, political actors hope that their messages will go viral through reposting or sharing across users and platforms. Indeed, it is difficult to think of a single major political figure in any democratic state who does not have a Facebook page with significant numbers of people who "like" or "follow" it.

There is some debate over the polarizing potential of political activity on Facebook. People are more likely to "friend" those who they know in the nonvirtual worlds of work, school, and more, and more likely to have a politically heterogeneous set of contacts on the site. Still, the opportunity to subscribe to updates from like-minded politicians and groups and to forward those posts and articles to one's friends creates the possibility of continued media selection and echo chamber dynamics. This is especially true given that it is easy to block the posts of people who politically disagree without actually "unfriending" them or losing access to chat, see their photos, or manually check their updates.

People can thus filter out those who disagree and further reinforce politically polarized social networks that extend to offline social relationships. Facebook's carryover effect into the real world makes political polarization that occurs via

its platform potentially more powerful and lasting since people are often interacting with others whom they care about, know very well, and/or view as trustworthy.

Anti-Polarizing Effects

Despite the wealth of research demonstrating the potential of social media to foster political polarization, there is likewise a significant body of evidence that demonstrates it can conversely be used for obviating polarization and increasing dialogue and even tolerance. In some instances, social media is even used as a simple means of information gathering for those wanting to make better informed decisions as voters, and can offer a genuine avenue for political persuasion.

Younger voters in particular are likely to gather information online. Prior to the rise of social media and social networking sites, this would have involved search engine queries, visits to major news and political sites, and perhaps a look at official party or candidate platforms on their Web pages. This information-gathering method is relatively passive and noninteractive, though it certainly makes access easier and faster. The addition of social media to this mix means that people can not only gather information online, they can also see how others are interacting with that information, including people whom they know from their own social networks, and who consequently would have a higher quotient of political trust. The type and nature of the discourse can widely vary depending upon the personalities of the social media users, nature of the topic being discussed, and use of escalating rhetoric within posts. The social media platform also has an important role to play in the type of discussion taking place.

Although Twitter is among the more likely platforms to have a polarized audience due to its use of hashtags and the ease of filtering information according to political preferences, it nonetheless has significant potential as a dialogue starter, not only because of the ease of use and rapidity of distribution mentioned before, but also because it is immensely popular as a publicity tool for sports figures, celebrities, and other public figures. In these cases it is entirely plausible that people may subscribe to tweets from people in public life that they enjoy in a public consumptive capacity, who

may nonetheless have political views that are not aligned with their subscribers. This is especially true of people in the film industry, who might hold leftist or progressive views, but whose fans often come from regions of the United States that are more conservative. Alternatively, some sports like NASCAR or music genres like country-western are more likely to feature people who are conservative, yet they may very well have more liberal fans who subscribe to their feeds for updates on their latest activities.

There are also far less influential Twitter feeds in terms of subscriber numbers that may have more impact on individual voters because any individual can have an account. This means that when someone subscribes to the feed of someone they actually know, and consequently are more likely to trust on political issues, they may be exposed to alternative political ideas, or at the very least to internal critiques and refinements, or partisan political messages. Polarization has pushed people more firmly into the U.S. two-party system, but that does not mean that there are not very distinct constituencies within them that have unique concerns and outlooks on particular issues, and thus provide an element of internal debate and self-correction toward a political mean.

While YouTube is relatively impersonal and more prone to online trolling and abuse, it is one of the primary sources of information for people looking to make informed decisions about politics. They can subscribe to channels from non-partisan sources, or even from direct government sources like the White House or Congress. This allows politicians to directly speak to voters without partisan news filters, though this does not mean people do not filter the news via personal partisan lenses. It is also an excellent resource for those who want to engage in and watch substantive political debates as various expert roundtables and even candidate debates are easily accessed on its portal. Although polarization does not disappear in these venues, they do make the existence of debate and the possibility of alternative political beliefs more concrete and could theoretically also foster greater tolerance for and awareness of divergent views.

Of all the most popular social media sites, Facebook is probably the most likely to foster

political tolerance and genuine discourse. This does not completely mitigate the polarizing influences of friend selection, the existence of echo chamber effects due to regional political trends, and social or religious networks, all of which will likely be reflected in a user's friends list. However, its key distinction is this very same personal relational element. As mentioned before, this is a crucial component of what is referred to as political trust. The more political trust a user has in someone else, the more likely it is that their opinions will matter and be influential. A lack of trust equates to an easier time ignoring information or opinions that run counter to one's own.

Various studies have been done on actual Facebook posts and their political content. These have generally rated the opposition factor of opinions and the tone of the discourse involved. To date, most of these studies have shown that discourse is surprisingly civil, and is centered on discussing the facts and merits of given political topics or candidates. Researchers Matthew Kushin and Kelin Kitchener, for example, have found that there is little evidence of widespread polarization on Facebook or at least that Facebook is not a causal factor in polarization in most instances. In fact, it was shown to potentially increase political tolerance and discourse precisely because the people involved already have personal relationships with one another that exist outside of a political context. This means that unlike many other online spaces where anonymity or at least the lack of offline connections exist between users, generating a sense of alienation toward other actors and general lack of accountability for how one behaves, Facebook actually encourages substantive and polite conversation because normal social rules apply as they would in the offline real world.

Conclusion

Improving the effectiveness of social media efforts is part of a major drive by both major U.S. political parties to increase turnout among voters. They are also seen as critical parts of building an online brand that can generate user loyalty, with the aim of ultimately improving not just voting but also citizen engagement with politics. Due to the use of social media platforms to republish material from partisan news outlets and other self-filtering sources, it often has the effect of amplifying the

echo chamber effect of people surrounding themselves with those who agree with them politically to the extent that they no longer view opposing beliefs as legitimate or even rational. Once one's opponents cannot even be seen as possessing logic and common sense, there is little ground left for respectful dialogue, let alone genuine compromise.

Furthermore, the viral nature with which information is distributed on these platforms and their emphasis on quickly grabbing attention and making political statements with the utmost simplicity and brevity means that polarization can be further worsened, simply through a lack of factual substance and grounding of political argument with observed effects in the real world. Ideology thus trumps experience and empiricism, and in this scenario, it is difficult to see any means of extricating political debate from this polarizing dynamic.

Despite these many tendencies toward polarization, social media, particularly as seen on sites like Facebook and in conjunction with nonpartisan open information and government accountability groups, can actually foster not only easier access to relevant political information, but also far more substantive and tolerant debate between people with divergent views. If these educational and relational components continue to rise in popularity as social media functions, then it may very well have a significant role to play in allowing political partisans to be exposed to alternative viewpoints, and even to hosting the conversations that are necessary for finding solutions that are acceptable, if not optimal, to people of all political persuasions.

Polis, Jared

Jared Polis is the U.S. representative for Colorado's Second District. First elected in 2008, Polis serves on the Committee on Rules and the Committee on the Judiciary. Polis is also a member of the Democratic Steering and Policy Committee of the House of Representatives. Despite his relatively recent tenure Polis leads as a Democratic Caucus regional whip, co-chairman of the New Democrat Coalition Education Task Force, chair of the Immigration Task Force of the Congressional Progressive Caucus, cochairman of the U.S.-Mexico Congressional Caucus, cochairman of the Congressional Caucus on Nepal, and co-chairman of the LGBT (lesbian, gay, bisexual, and transgender) Equality Caucus. Additionally, he is a member of the U.S. Air Force Academy Board of Visitors.

Polis and his parents created the online greeting card Web site www.bluemountainarts.com, later selling it for \$780 million. Polis launched ProFlowers on his own, an online florist that was eventually acquired by Liberty Media Corporation in 2006. By 2008, when he was elected to Congress, Polis was one of the 10 wealthiest congresspeople, worth approximately \$66 million.

In 2000 Polis signaled his commitment to educational opportunity with his establishment of the Jared Polis Foundation (JPF). The JPF runs the annual Teacher Recognition Awards to spotlight outstanding educators. It also administers

the Community Computer Connection program, which supplies schools and nonprofit organizations with refurbished computers—more than 3,500 each year. The JPF also produces a semi-annual report on education.

In 2004, Polis founded the New America School, which has four campuses that serve immigrants ages 16 to 21 years old. Polis next co-founded the Academy of Urban Learning, which helps at-risk Denver youth. He has received many awards for his philanthropic efforts, including the 2006 Outstanding Philanthropist, the Boulder Daily Camera's 2007 Pacesetter Award in Education, the Kauffman Foundation Community Award, the Ohtli of the consul general of Mexico, the Martin Luther King, Jr., Colorado Humanitarian Award, and the Boulder Community Builder Award through the Anti-Defamation League.

Political Career

In 2000 Polis began a six-year term on the Colorado State Board of Education. He served until his district was eliminated in January 2007. The election that brought him into this position was one of the closest in the history of the state of Colorado; Polis won by only 90 votes.

Starting in 2006, Polis joined Coloradans for Clean Government as cochair. On this committee he advocated for Amendment 41, which sought to ban lobbyist gifts to elected officials and established an annual \$50 restriction on nonlobbyist gifts. It further mandated a two-year waiting period for former elected officials who wish to begin lobbying, and established an ethics committee to be independently regulated. In 2006 the measure was approved by Coloradans.

In 2007 Polis cochaired a campaign for school bonds, which was approved. In 2008 Polis succeeded Mark Udall as representative for Colorado's Second District in Congress, and he was reelected in 2010. Polis is openly gay, and became the first gay parent in Congress in 2011.

In 2011 Polis and Senator Joe Lieberman sponsored the Race to the Top Act, H.R. 1532, which dealt with school innovation, charter schools, and teacher compensation. Polis also sponsored the School Lunch Improvements for Children's Education Act, SLICE, in response to the congressional definition of pizza as a vegetable. SLICE would require healthier meals for students, would

count tomato paste based on its actual volume, set targets for sodium reduction, and allow a U.S. Department of Agriculture whole grain requirement. SLICE is opposed by agribusiness giant the Food Institute.

Polis sponsored the Student Non-Discrimination Act, SNDA, with Senator Al Franken that would apply Title IX of the Education Amendments Act to LGBT students and therefore federally prohibits sexual orientation and gender identity discrimination in all schools. Work continues to make this a bipartisan enterprise because only two Republicans had signed onto SNDA by December 2012. Polis also sponsored the Defending Special Education Students and Families Act, which would fund the Individuals with Disabilities Education Act (IDEA). This legislation regulates how government agencies intervene in special education cases.

Colorado Congressman Jared Polis's speech titled "Financing Mechanisms for Developing Human Capital" at the TEDxBoulder event in 2010. Polis discussed how small investments in education could yield big results for the economy.

Polis also introduced the Computer Science Education Act, which was designed to provide computing vocational training. Polis also sponsored the ACE Act to provide funding for chronically low-performing schools.

Polis has consistently opposed the Iraq war. He also supports removal of all troops from Afghanistan. Polis voted in favor of sanctions against Iran. He has called for the U.S. State Department to investigate human rights abuses against LGBT Iraqis and to take action to stop violence against the Honduran LGBT community. An outspoken opponent of the USA PATRIOT Act, Polis has called for restoration of civil liberties and privacy rights in Congress. Polis was also critical of certain aspects of SOPA, PIPA, and CISPA, all acts designed to fight piracy, protect intellectual property, or allow online surveillance by authorities.

Polis is an active advocate for the LGBT community. He has called for the repeal of the Defense of Marriage Act (DOMA), and asked for the recognition of LGBT marriages in the United States as an original sponsor of the Respect for Marriage Act to repeal DOMA. Polis voted for the repeal of "Don't Ask, Don't Tell." Polis also cosponsored the Matthew Shepard and James Byrd, Jr. Hate Crimes Prevention Act, which would fund federal investigation of hate crimes, and has pressed for the inclusion of LGBT domestic violence victims in VAWA provisions.

Social Media Use

According to OhMyGov, at the end of 2012, Jared Polis enjoyed a Media Power Rank of 48th among 541 peers; Poleet.com also reported that Polis had a Klout score of 82. In December 2012 he had just under 19,000 fans on his Facebook page and more than 37,000 Twitter followers. In a 2012 interview with *Politico*, Polis said of his social media use: "I use these platforms myself, so they have an authentic voice. You're not going to connect with users with nothing but canned messaging and press releases. You have to 'get' the unique language of each medium."

In 2012 Jared Polis was the winner of the Member Online All-Star Competition among Democrats in the U.S. House of Representatives. This three-week-long competition, which was in its third year in 2012, was designed to boost the social media presence of Democratic members of

the House. Polis put his online experience and familiarity to work and campaigned on Reddit and on his profile pages. Polis is also a Second Life player, and has posted on the League of Legends forum with a positive response. House Democratic Whip Steny Hoyer announced in August 2012 that Polis was the winner, and that Democratic House members gained in excess of 139,000 new fans on Facebook, followers on Twitter, and subscribers on YouTube during the three-week contest. This represents a gain of more than 82,000 over the 2011 contest results. This was not Polis's first run as MVP; he also won the first contest in 2010.

Polis's Republican counterpart in 2012 was Congressman Justin Amash, the Republican New Media Challenge MVP. The Republican New Media Challenge is a nearly identical yearly contest in which Republican Representatives compete to attract the highest number of new followers on Facebook, Twitter, and YouTube.

Also in August 2012 (and in the wake of his MVP victory) Polis was highlighted by the Independent Voter News (IVN) in a feature called "The Social Ballot." This segment of the online publication is devoted to recognition of "politicians, candidates, and political organizations who are utilizing social media in effective and creative ways." IVN attributes Polis's likeability in the social media world to his personal management of his social media presence, his regular and consistent tweeting, and his attention to trending topics on Twitter.

Polis's social media intelligence is not limited to gaining new followers. He has also proven that social media use can be a very effective tool for advocacy. In December 2012 University of Colorado (UC) President and Republican Bruce Benson e-mailed alumni a warning about the UC risking a loss of almost \$1 billion based on the decriminalization of marijuana. The argument was that the UC receives a substantial amount of federal funding, and that federal guidelines prohibit marijuana use.

Polis was quick to respond on Twitter, denouncing the e-mail as "false" and attributing Benson's motivation to personal disagreement with Amendment 64, the decriminalization initiative. Polis tweeted that the amendment did not require that UC allow marijuana on campus, and

that just as alcohol is banned on campus despite its legal status, marijuana will also continue to be banned. Polis also e-mailed an official statement countering Benson's message. This rapid response in online fora highlights Polis's effective social media presence.

Political Base

A political base is a group of individuals that supports a candidate or party based on a set of agreed upon core values. The core values form the basis of a political agenda or platform. A

continuum for identifying a political base moves from left to right. On this continuum a left-leaning political base is more liberal, whereas a political base leaning right is said to be more conservative. Moderates, or those in the middle, may lean in either direction-based on the issue. Politicians have quickly recognized the advantage that social media such as Twitter, LinkedIn, Facebook, YouTube, blogs, text messages, and similar virtual tools, provide as instruments for keeping in touch with their political base. Other examples include GoToMeeting, which provides virtual presentations for anyone with Internet access. Skype has similar features and offers the opportunity for cheap or free calls. Politicians use these particular social media options quite often to make presentations and provide Webinars for their political base.

For most of the 20th century the dissemination of information followed a basic two-step flow theory. Paul Lazarsfeld, Bernard Berelson, and Hazel Gaudet introduced this theory in 1948, noting that procedurally, information flowed from radio and print media to leaders, and from leaders to the sections within the population who are overall the least active. In 1995 Deborah Baldwin, commenting on the interaction between interest groups and the Internet, stated that for interest groups, the Internet presented a new way of lobbying individuals and groups. The current environment and its strong reliance on social media has turned the two-step flow theory on its head: an individual sending a tweet, posting on Facebook, or sending a text may now also become a leader. The news is no longer entirely the possession of television, radio, and print media outlets.

Social Media and the Political Base

Politicians have come to use social media approaches like Twitter feeds, Facebook posts, texts, podcasts, and discussion forums as means of reaching their base. Robert Merton called leaders who can only manage one area of influence “monomorphs,” while those managing to influence several areas are “polymorphs.” In the current political environment, with the potential for a political base to be extremely varied, a politician must expand his or her range of influence on many different issues, as well as increasingly

the number of ways in which he or she reaches that varied political base.

Social media also offer the opportunity to gather information about various bases of political ideology while seeing responses to an issue develop in real time. Because social media do not include every member of a particular political base, at best, the results will only be conclusive for that particular group responding by social media; and at worst, the results will be limited in the perspectives that can be shared by the particular group responding via social media.

Contemporary writers remarking about changes in political bases and on techniques for reaching a base often cite the belief that, depending on the form, social media will have both a temporary as well as a permanent impact on base politics. Specifically, Malcolm Gladwell believes that social media’s influence has been exaggerated. He has called for caution regarding the use of social media for reaching a base in networks he sees as loose and leaderless.

Since the 1960s, politics have shifted, and issue influence has tended to crowd around visible concerns that spark emotion and action in a political base. Social media documents this shift in real time as noted by blog or article comments, tweets, or texts sent during a live debate on TV or radio. Social media also provides a steady stream of live numbers that can be easily captured. Prior to making a statement on an issue in the recent past, a politician would assemble his or her team of advisors and hash out a script to read to assembled supporters. Now, a social media specialist may first consult on where to place the content. This base can be local, state, national, or global, and an effective consultant could make a judgment on the reach and base in a matter of minutes.

International Reach

A local political base is not the only base of supporters that social media can reach on a daily basis. A global political base can also be accessed for ideas and suggestions as they receive communications once limited to traditional media, airmail, faxes, or personal visits. The notion that any leader of any country can stay in contact with his or her political base from abroad is now a way of life. At any time, a leader can visit another country, make a speech in that country

on an issue or a concern, and have that speech streamed live by any number of social media outlets. Anyone watching the streaming version of the remarks can instantly become a part of the political base, thus making any issue around any subject a potential international issue. These additions to the political base come with the opportunity for further information dissemination, collaboration, and opportunities for additional means of funding for particular projects.

Today, a political base has become a virtual community. The 2011 Arab Spring is an example of a political base that expanded with every tweet, Facebook update, and text message to include new supporters from around the world. When these users are a part of a political base, the core values that were once so simple may become more global in nature and design. Politicians who understand this will become the leaders of the future, directing an ever-growing and ever-changing population of supporters.

Political Economy

The political economy of social media refers to the effects of capitalism in shaping, affording, and constraining social media, as well as to the role of social media in capitalist society. The term also refers to the intellectual paradigm that investigates social media in the context of capitalist society.

Drawing on the Marxist-inspired political economy of the (mass) media, the political economy of social media seeks to uncover the social, legal, cultural, and technological arrangements embedded in social media, and examines the social implications of such arrangements. The political economy of social media, then, investigates social media as economic organizations operating within the contours and logic of a capitalist society, and at the same time seeks to decipher the role of social media in the economy at large.

At the most fundamental level, the political economy of social media assumes that the new space of social media cannot be thought of merely in terms of the technology that enables it or the communication forms it affords; rather, it is also set within the broader socioeconomic space of capitalism. Social media is commonly treated as a new means of communication, enabling new forms of expression and social exchange in varied spheres, from political mobilization to economic activities. The political economy of social media, however, attempts to locate social media as caught within the Web of capitalist political economy. Rather than viewing social media as a transparent, neutral communication tool, the political economy of social media points to the ways by which it embodies and constitutes social power relations. Most fundamentally, the fact that the most prominent social media Web sites are owned by commercial companies is not incidental to the analysis of communication, but is rather highly consequential. Countering the hegemonic approach that focuses on the communication that takes place within social media, the political economy of social media focuses on the Web of social power relations established through this seemingly neutral technical platform.

Like any voluntary market exchange, in social media, both parties act out of self-interest and gain something from the exchange: Consumers

use social media for free and producers sell advertising space. Contrasting this view of a market exchange between equals, the political economy of social media sees social media as embodying power relations. While few dimensions of power relations emerge as central themes in the political economy of social media, they all seem to collate around the focal point of audience labor. It would be useful then to organize this discussion around this key concept, not least because of its roots in the political economy of the mass media and its link to a central debate in political economy generally about the labor theory of value.

Such an analytical move would also allow the underlining of how the political economy of social media is different from the (traditional and established) political economy of the (mass) media. And last, exploring audience labor would allow one to offer a political economy critique to the notion of “participation,” which in popular and academic discourse is seen as the key revolutionary aspect of social media.

Audience Labor

The notion of audience labor emerges as a critique of traditional political economy of the media, which regarded audience as located outside the sphere of (capitalist) media production. Traditionally, the political economy of the media analyzed media as a means of production in capitalist society, investigating issues of media monopoly, media corporations’ mergers and consolidations, links between government and the media, and employment schemes of media workers. The essential claim of this approach was that all elements of the media ecology, such as media corporations, journalists, and public service broadcasters, cannot be understood outside the institutional and structural positions they occupy. News organizations are also commercial enterprises thriving on the sale of advertising; news reporting may be constrained by legal or regulatory dictates; and journalists are wage earners. The political economy of the media sought to highlight those economic and political facets and investigate which effects they have on the media and in turn, on society.

Traditionally, then, the political economy of the media considered the audience as laying outside of the accumulation process, as passive

consumers of media content. In 1970, the political economy of the media was greatly revised by Dallas Smythe, who analyzed media as a site of production unto itself, thus highlighting the productive role of the audience in the creation of media value. He suggested that what goes on in the mass media was not primarily audience consumption of media content but the selling of audience attention to advertisers. This formulation rendered the audience an active participant in the political economy of the mass media. The audience performs cognitive and emotional work—learning to desire and buy commodities—and it was the attention of the audience that was sold as a commodity to advertisers. This rendered the media a vital component in the chain of capital accumulation. In return for the “bait” of programming, the audience remains glued to the television screen, thus watching advertisements, which become an ever-important driving motor for consumption. Smythe assigned the mass media and the audience central roles in advanced capitalism: the audience is put to work in marketing commodities to itself.

As a theoretical outlook and a research program, the political economy of the media emerged during and within the context of the mass media. The emergence of social media poses new challenges to this approach, given some fundamental differences pertaining to the relationship between the media and its audience. Social media companies provide the audience a platform for communication rather than content, and the seemingly passive audience has been rendered into active “users,” critical to the production of the media. These transformations in the relations of production between audience and media has also led to a change in the research program. While in the political economy of the mass media, the notion of audience labor remained relatively peripheral; in the political economy of social media, it has focused on the labor process as well as its product.

The centrality of audience labor in the political economy of social media is anchored in the increased involvement of the audience in the production of media. Indeed, the popular discourse on social media is dotted with a variety of terms describing new production practices and new products entailing audience involvement facilitated by social media: cocreation,

mass collaboration, social production, commons-based peer production, mass customization, prosumption, produsage, crowdsourcing, open source, social production, user-generated content, user participation, folksonomics, and wikinomics. Take, for example, the category of the media “prosumer” (or “produser”). Whereas in traditional media, there was a relatively clear-cut separation between producers and consumers of media content, social media is characterized by the blurring of these boundaries. Consumers (or users) are at once also producing that which they consume. This is seen in popular discourse as empowering individuals, rendering the passive audience of the mass media into the engaged audience of social media.

While popular discourse celebrates these new modes of media production as having empowered the audience, the political economy of social media uncovers new relations of power that these modes create, pointing to the ways by which these multiple production forms enhance the ability of media companies—compared to the mass media—to mobilize audience labor into capitalist accumulation. The political economy of social media seeks to explain how value is created in social media sites, and uncover the role of the audience in the creation of its value.

The audience of social media may potentially work more, create more surplus value, and be more exploited than was the case in the mass media. It participates in three moments along the value chain of social media. As in the mass media, an audience is mobilized to watch ads, leading to consumption. However, relative to the mass media, in social media, advertising schemes tend to blend commercial messages with social communication, thus leading to greater consumer mobilization. For example, Facebook’s Sponsored Stories are regular posts rendered into ads, thus representing both a real-life event and a commercial message, and are regarded as more effective than conventional ads.

Audience Data

The audience of social media is central in two additional moments of the value chain. First, the networked and interactive nature of social media and its affordance of audience participation enables social media companies to access a huge

amount and variety of data produced by users. Such data includes demographic and personal information, content of communication, online and offline behavior, and metadata about online usage patterns. This huge amount of data—leading to the establishment of big data “warehouses” of social media companies—is a key force of production in an information economy, an economy that thrives on data, information, and knowledge. Big data allows an intimate knowledge of the audience, both as individuals and in aggregate. The ability of social media companies to have (free) access to such big data—produced by the audience in return for (free) platforms—and commodify it is at the heart of their business model, which is the sale of advertisements, which become more personalized and targeted.

An example of the commodification of big data is predictive analytics, which seeks to predict individuals’ consumerist behavior and bolster it. To a large extent, predictive analytics based on big data substitutes statistics in providing knowledge about human behavior based on real-life data (rather than data collected from interviews or surveys) and the whole population (rather than a sample of the population).

One issue emerging from the production of data is a new form of inequality between audiences using social media and companies that own them—dubbed the “big data divide”—which is based on differential accessibility to the data. While the audience produces the data, only social media companies can access it. The valorization of personal, mundane data, produced through what the autonomist school of Marxism refers to as “immaterial labor,” is a testament to an increased reliance on life itself—taking place outside the traditional sites of production—in contemporary capitalism.

Social media are technically and ideologically structured to make users produce as much data as possible. Indeed, what goes on in social media is not primarily the collection of pre-existing audience data, but rather the production of data by the audience, data that has been hitherto almost inaccessible to harness for capital accumulation, including personal, communicative, mundane, and behavioral data. Such data are produced within the context of regular communication and the sociability of social media users.

In addition to watching ads and producing data, the audience also engages in marketing. Social media audiences construct and maintain multiple networks within social media, which are founded on—to varying degrees—familiarity, similarity, and mutual trust and influence between networks' members, as well as affording them a peer-group, sharing common interests and lifestyle. The “viral” or “organic” nature of commercial messages in social media (as they are called in advertising lingo) derives precisely from the construction of such networks, and leads to a new type of audience labor where audience members do not merely market products to themselves (as Smythes put it), but also market products to other members of the audience.

Surveillance and Privacy

Notwithstanding the importance of consumption and marketing, it is the production of data and metadata by users that lies at the heart of the political economy of social media. As audience-generated data becomes a central force of production, an inextricable link is created between social media and surveillance because audience data needs to be accessible to social media companies in order to be commodified. The political economy of social media is conditioned by the willingness of an active audience to surrender private and personal data to social media companies, and often also to third-party companies; by construction, such data loses its status as private. The centrality of surveillance to the political economy of social media poses a threat not only to privacy, but as noted above, but also affects the way that social media is designed in order to maximize the production of media, and may be consequential in terms of inequality (i.e., the big data divide).

More broadly, this issue points to the contradiction, embedded in social media, between social norms that consecrate privacy and a political economy that thrives on surveillance. This has indeed been an issue of intense public debate. In a similar way, and leading to much public debate as well, is the intrinsic contradiction between social norms and institutions consecrating private ownership and authorship over products, and the collective and social nature of production in social media. In contrast to the mass media, social media companies are able to create big data, and

audience members are able to communicate with each other, cooperate, and collaborate. By construction, then, the product of audience labor is communal. A Google search result is based on previous queries of users, and a user's Facebook news feed is a communal product of other users. The legal and normative institutions of intellectual property rights were founded on the notion of a cultural product having a single, recognized producer or author. They were construed in the context of the mass media and fitted its political economy, which assigned media companies with exclusive rights over content.

Noncommodified Social Media

Social media undermines the foundations of this normative arrangement since the product is by construction collective, representing the “general intellect” of the audience. In reality, sparse efforts have been developed, alongside the hegemonic capitalist model of private intellectual property rights, to build nonmarket based projects of social media, the most exemplary of which is Wikipedia, the online collaborative free encyclopedia. As are all social media, Wikipedia is also the product of audience labor; but unlike commercial social media, audience labor on Wikipedia is not commodified. Such and other exemplars of noncommodified social media have led political economists of social media to point to an alternative political economy that would reconstitute social media as the commons—noncommercial, common, cultural products to which everyone contributes and has access to—as a project that transcends the contradictions of contemporary capitalist social media. The political economy of social media, then, proposes to radicalize the notion of social media by suggesting that its production is truly social, and hence its value should also be socially shared rather than privately owned.

Conclusion

The political economy of social media also points to the ideological role of the media in justifying its model of political economy and the political economy at large. In the mass media, political economists have pointed, for example, to a press that accepts the basic premises of liberal democracy and capitalism, to the content of programs naturalizing racial and gender inequalities, and to

advertisements advancing a consumerist lifestyle and facilitating a consumerist society. The analysis of social media has pointed to the ideological mechanisms that drive audiences to produce as much personal data as possible: from the dictum to share one's mundane life with others through text and photos, to the call for audience members to be part of an emancipatory, participatory, democratic, antielitist and collaborative culture, and express themselves—all of which are aimed to encourage audience labor in social media.

At the heart of the political economy of social media are two contradictory trends. On one hand, social media represents the unprecedented “socialization of communication,” where the means of communication are democratized, where every Internet user can communicate, tweet, create a blog, be a citizen journalist, and be part of a custom-made social network. Socialization here refers not only to the decentralization of expression to each member of the audience, but also to the ability of users to cooperate among themselves on a social-wide scale—communal, national, or transnational—and create a media that is radically social, of the people, by the people, for the people.

On the other hand, social media also represent a trend toward the unprecedented “commodification of communication.” The audience's social communication is increasingly commodified and sold on the market, becoming a staple force of production in the political economy of social media. Social media sites are predominantly commercial spaces, structured and run according to the rationale of capital accumulation rather than social communication. As immaterial products of data and information, communication and sociability become increasingly important forces of production in contemporary capitalism, and as their production is increasingly taking place within digital media, so the commodification of communication ensues.

These two trends are dialectical; they are contradictory and complimentary, and above all tenuous and dynamic. The more media is socialized, the more it mediates the production of social communication and in turn boosts the commodification of communication. At the same time, the socialization of communication, the ability of the audience to communicate among itself, may also

undermine and disrupt commodification, as is the case with Wikipedia, where the socialization of the media led to the creation of a knowledge commons rather than commodification.

The trend toward the commodification of data and communication and the exploitation of audience labor occurs along with enhanced opportunities for the audience to express themselves, collaborate with each other, and participate in the reproduction of society through a fairly accessible media. Indeed, the political economy of social media is founded on social media being a juxtaposition of a means of communication and a means of production, an arena for sociability and a site of labor. These trends are also dialectical: they feed into each other, but can also disrupt one another, leaving the field of political social media dynamic and open for change.

Political Information Opportunity Structures

Social change triggered by popular movements occurs when the actions of like-spirited individuals whose shared values and goals related to particular

A protest in Boston on June 20, 2009, in support of the Iranian Green Movement and condemning the Iranian government's violent response to protesters in Tehran. The current information environment allows groups to organize and demonstrate without long-term planning or extensive resources.

issues mobilize them to sustained collective action, generally moving forward in stages. However, not all social movements will survive the early stages of emergence and coalescence. The importance of context or sociopolitical structures is critical to understanding which social movements will fully develop and how they might do so.

Social Movements and Political Opportunity Structures

Sociologist Robert Merton established that societies are dynamic, sensitive to functional (and dysfunctional) outcomes of actions, with social institutions ultimately emerging as the integration of factors. Michael Lipsky observed that social movements tend to progress in stages and waves, with potentials and outcomes dependent upon many variables. Merton emphasized that institutional structures are not the only providers of societal survival functions, but that a variety of social and cultural alternatives exist, including the “deviant” actions of social movements.

Social scientists use the concept of “opportunity structures” to examine factors external to the movement or individuals within it that inhibit or facilitate the viability of a particular movement

in a particular time and place. Peter Eisinger, in his study of 1960s-era riots in 43 American cities, coined the term *structure of political opportunities*, stating that these opportunities emerge from the cultural mood and ideological climate of a given time and place. They arise from situation-specific “soft spots” that might offer fertile ground for social movements to take root and develop. The structuralist approach emphasizes that the importance of those factors external to the movement are at least as important as factors relating to the goals, values, and characteristics of actors within the movement.

Sociologist Douglas McAdam, an early theorizer of the “political process model” for social movement analysis, explained that these external factors (or political opportunity structures) can be described along four spectra: (1) how open or closed to action the political institutions within a particular field of action are; (2) how stable or unstable the collectivity of elites who are operating at that time and place is; (3) whether or not those elites are affiliated with other entities outside their collectivity; and (4) whether or not the political institution(s) governing a particular field of action are willing and able to repress the movement. The particular integration of positions along these spectra can expand or contract political opportunities for the social movement, for other social movements, for opponents of the movement, or for elites and their allies.

Media Regimes and Political Information Opportunities

While shared norms, customs, traditions, values, and institutions have been the ground on which sociopolitical movements have taken root prior to the 21st century, the basic building block now is information and access to channels that empower actor-agents to construct and disseminate social meanings. Now, informational bonds construct sociopolitical bonds. Technological channels not only impact the venues and contexts of political interaction, they also construct them. Government is embedded in its publics in a radically new way and is increasingly vulnerable to networked collective action locally mobilized via global information technologies. Information fields are vastly expanded and far more complex, with fewer gatekeepers. Access to politicized information and the

power to transfer it widely is, with the emergence of digital communication modes, information technologies, and the global networks these generate, a new form of opportunity structure.

Bruce Bimber, political scientist and founder of the Center for Information Technology and Science at the University of California, Santa Barbara, has contextualized the current technological revolution and its impact on American democratic processes within a historical overview of the relationships between political information and institutional adaptations to advances in informational linkages. Bimber calls the current information environment—the rise of the Internet—the “fourth information revolution,” the key characteristic of which is “information abundance.” By this is meant that virtually anyone can produce and distribute it worldwide at little or no cost.

In this era of “post-bureaucratic pluralism,” the power to act quickly, effectively, and economically has produced what Bimber calls a new “media regime.” Absent the need for formal organization or interest groups, long-range planning, and extensive resources, some theorists expect increased political participation on an increasingly democratized field of action. Other theorists take issue with what they see as an over-application of the concept of “political opportunity.” These theorists fear that in attempting to offer a broad and comprehensive explanation, concrete and useful application will not be possible, especially because there appears to be a lack of consensus as to what a “political opportunity” actually is.

Nevertheless, the centrality and effectiveness of social media in generating, mobilizing, and sustaining the wave of revolutionary demonstrations and protests in nearly two dozen countries in the Middle East and north Africa beginning in December 2010, collectively named the Arab Spring, has been extensively studied. The relationship between social media (or “rebellious communication”) and social movements generally is a growing subdiscipline of sociopolitical research; other focuses have been the Occupy Wall Street movement, the Iranian Green movement, animal rights activism in Poland, women’s social networks in the United Kingdom and Germany, and *Kony 2012*, the viral video about Ugandan warlord

Joseph Kony, which was reportedly viewed by up to half of young Americans, having tallied over 100 million views within six days of its release.

Political Parties

Political parties use social media to provide information, communicate about party issues and candidates, connect constituents and politicians, and ultimately to mobilize supporters to take action through volunteering, voting, or spreading the word. The two major political parties in the United States have taken different approaches to

the use of social media, while third parties seek to build social media capital through networks of online supporters, hoping to mitigate the financial disadvantage that they face during political campaigns and their exclusion from public debates. The Democratic Party, particularly during the 2008 and 2012 campaigns of Barack Obama, has incorporated social media into every aspect of its political campaigns.

In the 2012 election, both parties were expected to spend a record percentage of their advertising budgets on Internet advertising. While the Republican Party has also employed various social media platforms, it has not been as active in using them as tools for mobilization and engagement for constituents and supporters. Third-party candidates and supporters depend on social media to establish a presence in a market that requires significant campaign cash to compete for advertising time on broadcast media. In terms of content, the Democratic Party and the president also employ a more visual strategy when it comes to social media, relying on images and graphics with stylized text that are designed to be easily shared on any social media platform. For both Democrats and Republicans, especially during campaigns, social media activity is centered on the accounts of national candidates.

Ideologies

The United States is dominated by two major parties, representing two major ideologies, it is useful to examine how the parties' use of social media reflects their underlying ideologies, most commonly defined as conservative and liberal. Conservatives favor individualism, tradition, order, and well-defined structures of power. Liberals promote notions of equality, collective responsibility, and inclusion. Thus the Democratic conversation in the United States is about the value of collective rights and responsibilities versus the rights and responsibilities of the individual, and the role of government in facilitating those differing priorities. As many scholars have noted, social media may be a more hospitable environment for citizens with liberal values, who are generally more tolerant of the chaotic, democratic nature of online discussion. The Pew Research Center found that citizens who describe themselves as "liberal" consider social

networking sites a valuable source of political news to a much greater degree than citizens who describe themselves as "conservative" or "moderate," although there were no significant differences between liberals and conservatives in overall use of social media. There is also, however, evidence to support the theory that social media's ability to distribute both authored and anonymous messages quickly, widely, and often spontaneously exacerbates political polarization on both ends of the liberal/conservative continuum.

Social media provide political organizations and actors with a two-way channel of communication. Members of the online public are able to respond to and reframe messages, and can serve as amplifiers or spoilers of a party or politician's preferred narrative. The Democratic Party advantage may be attributed to three factors. The first is the Obama campaign's early adoption of social media as a medium for speaking directly to supporters. The second is the recognition that effective use of social media means entrusting supporters to not only share campaign messages, but also to craft them. The third dimension of this strategy comes from the daily generation of content by the campaign, through both a candidate channel and official White House channels, which provide a constant stream of "president at work" messages and images.

Political parties are also represented in social media on the state and local level, by party accounts as well as local candidates, organizing and speaking to constituencies in their communities. At the national level, the tasks of communication and information are the focus, and supporters play a critical role in distribution of messages through sharing and retweeting. Both Democrats and Republicans maintain Facebook pages for their congressional and senatorial campaign committees, and both have attracted as many "likes" as the official party pages.

During the 2012 national elections, the Democrats further integrated social media into its campaign, creating a social media-style dashboard that allowed real-time tracking of volunteers and their campaign activities, thus maximizing the campaign's time and resources. The dashboard also provided the campaign with constantly updated information about voters. Post-election, President Obama has continued to regularly use social media

in his efforts to move legislation forward, encouraging citizens to contact members of Congress through Twitter and Facebook and express their support for his agenda. Using empirical methods, the Analyst Institute, a think tank organized and funded by progressives, continues to pursue data-driven strategies for connecting to and mobilizing voters, strategies that are fully grounded in the cell phone, Internet, and social media-connected world. For the Republican Party, the election campaign of Mitt Romney saw the development of an application dubbed ORCA, a voter tracking system that was criticized by campaign watchers as ineffective and undertested. This battle over the technological tools of persuasion and motivation represents an entirely new front for political campaigns.

Social Media on Official Party Web Sites

The official Web pages for the Democratic and Republican parties are similar in design. However, the content is presented quite differently, with the Democratic Party opting for visually focused content, providing images of the president, as well as talking points presented in stylized graphics that are designed for social media sharing. Both parties have included tools for social media-sharing on their pages, but in slightly different ways. On the Republican page, each page has a floating “share” button, requiring clicking through headlines to individual pages, which can then be shared on social media. On the Democrat’s homepage, stories are presented on the home page with “share” buttons, requiring one less click for sharing to Twitter, Facebook, Google+, and other sites.

Facebook

Typing “Republican Party” into the Facebook search function does not bring up the official Republican Party page. “Republican National Convention” brings up the official “GOP” page with over one million “likes.” Typing “Democratic Party” immediately brings up the Democratic Party Facebook page, with the recently updated, minimalist logo design. This page has over a half-million “likes.” Both party pages represent miniscule followings in comparison to their national candidates, with Mitt Romney and Barack Obama listing more than 11 million and 33 million “likes,” respectively, on their individual

pages. President Obama also posts on Facebook as “The White House,” a page that has just over a million subscribers.

President Obama posts on Facebook every day, sometimes multiple times per day, sharing content that is overwhelmingly positive, and primarily visual—smiling faces, images of the family and the family dog, and images of President Obama interacting positively with citizens. This approach is consistent with findings by the Pew Research Center, which suggest that users of social media see them as environments for primarily positive exchanges and content. There are frequent posts with humorous themes. There is consistency, although not duplication between the “White House” page and the “Barack Obama” page. For example, on the “Barack Obama” page, the image posted to celebrate Thanksgiving 2012 was a snapshot-style portrait that was clearly taken before the 2008 election, of a much younger Obama family, while the “White House” page shared a family photo that was a recent, and very formal, White House portrait.

Candidate Mitt Romney and the Republican National Committee (RNC) were not as frequent with their postings, and generally not as playful as the posts made on behalf of the president. Humor is rarely employed, nor are the posts as image-heavy as those of the Democrats. The RNC posted a single sentence wishing subscribers a “Happy Thanksgiving,” while former candidate Romney posted an image of himself and his wife posed quite informally in their kitchen, a post that stands out on his Facebook page as uncharacteristically intimate. The post was shared more than 16,000 times, in comparison to the RNC’s text-only greeting, which was only shared by 104 people. It is clear that for politicians and parties, a compelling image can dramatically increase the chances that a post will go viral on Facebook. In fact, the record for the most “liked” image ever on Facebook is now held by the Obama campaign by its celebratory message posted as results were announced in the 2012 election.

Twitter

President Obama’s advantage of three to one on Facebook is even more dramatic on Twitter. Governor Romney amassed 1.7 million followers during the 2012 presidential campaign, whereas

President Obama has more than 20 million Twitter followers. In comparison, the Democratic Party official Twitter account (@TheDemocrats) has only 200,000 followers. At just under 200,000 followers, the Republican Party (@GOP) Twitter account is similarly dwarfed by its most recent national leader.

Twitter limits users to 140 characters, but allows for embedded content from image-sharing sites, including YouTube and TwitPic. It favors the clever retort over the long-winded argument, and allows users to address any other Twitter user via the @ symbol, known as a mention, whether they are connected through “following” or not. Twitter was widely used during the presidential debates of 2012 in a practice known as “live-tweeting.” The most striking aspect of live-tweeting was the instant emergence of memes that influenced news media coverage of the debates. At other times, Democratic and Republican citizens can be found tweeting with the hashtags #p2 and #tcot. In this way, participants on Twitter connect with like-minded citizens, and also seek to provoke and engage political opponents.

YouTube

Both parties maintain a channel on YouTube. Neither of the party channels is very active in comparison to the channels of their most recent national candidates. The RNC channel has more views than the Democratic Party channel. Again, President Barack Obama has established an audience that dwarfs his opponents and his party to an exponential degree. Results of YouTube searches also demonstrate how candidates benefit from an active online following that creates and redistributes media among themselves. Searching the candidate or party name produces a number of user-generated tribute videos for President Obama, while critical parodies and satire are prominent in the search results for “Republican” and “Mitt Romney.”

Other Parties, Other Platforms

Politicians and parties seem to have focused most of their attention on Facebook and Twitter, but the Democratic Party can also be found on Pinterest, as well as the mobile phone image-sharing application Instagram. The Republican Party is not easily found on these platforms. President

Obama has a Myspace page that has been idle for more than a year; the parties are not present there at all. While the parties do not have a significant presence on Tumblr, a site that is dominated by a young demographic, President Obama does have an account, “ObamaFamily,” which posts a stream of images from the official White House photographer. Third parties such as the Libertarian and Green parties have a presence on Twitter and Facebook, but their followers and subscribers represent a proportion of citizens that is similar to their nominal percentage of the popular vote in federal elections.

Conclusion

For political parties, social media has generated a new landscape that must be navigated, but also one that provides opportunities to maintain an ongoing conversation between politicians and constituents. The Republican Party has established a presence on social media sites, but has not yet fully deployed strategies designed to take advantage of the unique features of social media. Visual content, including many images of smiling faces, and political positions expressed as easily sharable graphics are the assets that are most likely to encourage supporters to share and retweet to their friends and family. The Democrats are also easier to find on social media, maintaining a consistent image across platforms.

The disparity between followers of high-profile politicians and parties raises the question of how parties can create and sustain a coherent social media presence when terms are over or politicians are unsuccessful in an election or re-election campaign. For the Democrats, Barack Obama has become the face of the party in the realm of social media. The challenge for his party will be to redirect his followers once his second term is over. For the Republican Party, this question is even more urgent because the party out of power finds itself without a national representative between presidential elections.

Politico

Politico is a fast-paced, innovative Web site (and accompanying newspaper) with an audience of 60 million visitors. The site changed the face of political news reporting by helping bring the news cycle down to 15 to 20 minutes, as opposed to network coverage that is typically on a 24-hour cycle. *Politico* is staffed with over 150 employees working to provide a mixture of politics, trade journalism, real-time chat, blogs, information on political jobs, and advertisements in a minute-by-minute format. Through the use of social media, *Politico* delivers political news and conversation in a real-time manner.

Launched on January 23, 2007, by Editor-in-Chief John F. Harris, Executive Editor Jim VandeHei, and Publisher for Allbritton Communications Robert Allbritton, *Politico* has quickly become one of the leading nonpartisan news media companies, covering national politics and Washington, D.C., news. *Politico's* daily newspaper has a circulation of over 30,000, is distributed free on Capitol Hill, and features content on the president, Congress, lobbyists, and media. In addition to the site and newspaper, readers can access and participate in *Politico's* conversation

through Twitter, Facebook, TV, and radio. Owned by Allbritton Communications, *Politico* is affiliated with the ABC Network, which is owned by the Walt Disney Company.

Editor-in-Chief John F. Harris has worked in journalism for over 30 years, working for *The Washington Post* as a reporter for 20 years until becoming interested in editing. Harris posits that becoming an editor allows one to become immersed in conversations about the future, contemplating "What's next?" During his brief editing career at the *Post*, Harris worked with then editor VandeHei, who had over 15 years of experience reporting on Washington politics. They began brainstorming about collaborating on a new political publication. In 2006, Robert Allbritton, chairman and chief executive of Allbritton Communications, offered Harris and VandeHei the opportunity to start a nonpartisan media company, which became *Politico*.

Though *Politico* continues to be a successful political news organization, the progressive watchdog group Media Matters for America has accused it of having a Republican slant. Media Matters for America is *Politico's* strongest competitor, and has also been accused of being a "mouthpiece" for President Barack Obama. Despite *Politico's* naysayers, it has proved that people want to read "fast, fresh, and forward looking news." It is this type of trend-setting reporting that gives *Politico* an edge over its competition. Media critics have given it mixed reviews; however, the positive reviews largely outweigh the negative ones.

Politico has embraced new technology, providing its audience an opportunity to download apps for smartphones, receive e-mail alerts, and voice their opinions on blogs. The newer forms of social media allow *Politico* to distribute stories that can instantaneously drive the conversation about politics and government. Erik Wemple, a media critic who writes for the *Washington Post's* Web site, says that *Politico* has a credibility that comes from old media combined with the speed, TV, and social-media tools that define new media.

Politico's innovative means of news reporting on Capitol Hill, Congress, and the president now has a spinoff Web site called *Politico Pro*. *Politico Pro* is a subscription-only product launched in February 2010, reporting on policy in a *Politico* style. According to social media critics, *Politico* is

for political “news junkies,” whereas *Politico Pro* is for political insiders.

PolitiFact.com

PolitiFact.com, begun in August 2007, is a Web-based project of the *Tampa Bay Times* and partner news operations. The Web site researches and rates for accuracy statements made by public officials, including the executive branch, members of Congress, candidates, political party leaders, political activists and political action committees (PACs), advocacy groups, lobbyists, officials at all government levels, those testifying before Congress, and those who contribute to discourse in American politics such as pundits, columnists, interviewers, and talk-show hosts, and even widely circulated chain e-mails. They research statements using original reports,

original sources, and impartial experts, rather than news stories; the end results of multiple sources and original reporting reflects its goal of arriving at the truth. The final step is a rating of the accuracy, truthfulness, or status of promises made in the statements.

The *Tampa Bay Times* (originally the *St. Petersburg Times*) was owned by the Poynter family since 1912. In the 1970s, its owner Nelson Poynter (who also cofounded the *Congressional Quarterly* with his wife Henrietta), devised a plan to keep his paper independent. He created a small nonprofit school for journalism, originally called the Modern Media Institute (later renamed the Poynter Institute), and left the school his shares in the Times Publishing Company (which owned the newspaper) when he died in 1978. Control of the newspaper is unique: a single executive manages all operations and then picks the successor. Partner news organizations, include newspapers such as the *Atlanta Journal-Constitution*, *Cleveland Plain Dealer*, *Austin American-Statesman*, and *The Oregonian*, as well as one radio partner, New Hampshire Public Radio.

Launching PolitiFact

PolitiFact, the paper’s Web-based project, accepts underwriting funding from foundations involved with the improvement of civic discourse or news coverage, such as the Knight Foundation, Craigslister Charitable Fund, and the Collins Center for Public Policy. However, PolitiFact claims that it is an independent, nonpartisan news organization that does not answer to any corporate, political, or government interest.

Launched in August 2007, initially to fact-check the 2008 presidential race, it expanded in January 2009 to fact-check members of Congress and the White House. In 2009, PolitiFact was awarded a Pulitzer Prize for News Reporting for presidential election coverage in 2008. PolitiFact has developed a number of rating tools that evaluate the accuracy of statements or the solidity of positions. The Truth-O-Meter, the centerpiece of the Web site, investigates the accuracy of discourse by candidates, elected officials, political parties, interest groups, pundits, and talk-show hosts. Among the guiding principles for Truth-O-Meter ratings are the precision of the statement’s wording and the context in which the statement was made.

Although PolitiFact tries to verify statements, the burden of proof for providing evidence to substantiate claims is on the person who made them.

PolitiFact staffers read many statement sources daily, including news reports, press releases, advertisements, Web and Facebook postings, speeches, and interview transcripts. They select which statements to research, report on, and rate for accuracy, based on a series of criteria involving the significance of a statement, the likelihood that a statement will be repeated by others, the verifiability of a claim (they do not fact check opinions), and the perception that a statement leaves an impression that may mislead or cause the audience to wonder “Is that true?” Recent topics range from gun control to sexual assault in the military, and from immigration reform to terrorism.

After an article is written and edited, it is reviewed by a minimum of three editors who establish a panel that assigns the rating. The ratings are offered in a hierarchy: the lower the rating, the more the deceitfulness (or the less truthfulness). A rating of “true” means that the statement is accurate, with nothing significant missing. A statement rated as “mostly true” is accurate, but needs additional information for clarification. If rated “half true,” a statement exhibits partial accuracy, but leaves out details or presents information out of context. A rating of “mostly false” means that there may be an element of truth but the statement ignores information that would offer a different perception. If a statement is not at all accurate, it is rated “false.” The lowest rating, given to statements that are ridiculously false, is “pants on fire.”

Each Truth-O-Meter rating is accompanied by a list of sources and includes links to those sources so that readers can decide if they agree with the rating. An annual “Lie of the Year” has been awarded since 2009, with the first going to Sarah Palin’s claims of the government death panels that would result from the Patient Protection and Affordable Care Act (also known as Obamacare). The same issue garnered the 2010 award for opponents who claimed that the act was a government health care takeover. In 2011, the Democratic Congressional Campaign Committee was cited for claiming that Congressman Paul Ryan’s budget proposal would end Medicare, which was untrue. Republican presidential candidate Mitt

Romney gained the 2012 award for his false claim that President Obama had sold Chrysler to Italian nationals so that they could build Jeeps in China.

Another rating feature is the Flip-O-Meter, which rates the consistency of an elected official’s issue positions. Rather than providing a value judgment of shifting positions (which might demonstrate an ability to compromise or adapt), the articles presented with the Flip-O-Meter offers analysis of the shift and then rates the amount of change based on three ratings. It follows the identical standards and process for writing, editing, and rating. A “no flip” rating signals that there was no significant change in position. A partial change rates a “half flip.” A total alteration of the initial position receives a “full flop.”

Promise Meters rate the status of campaign promises made by elected officials. The first was the “Obameter,” which compiled over 500 campaign promises made by Barack Obama during his presidential campaigns in 2008 and 2012. Campaign promises are rated as “not yet rated,” “in the works,” or “stalled”; if an action has occurred, it is rated as “promise kept,” “compromise,” or “promise broken.” A summary of the status of all promises is created, and the Obameter also sorts promises by subject, such as energy, taxes, the economy, and the military. An additional Promise Meter, the “GOP Pledge-O-Meter,” reviews Republican congressional leader promises made during the 2010 campaign, and uses the same rating system.

PolitiFact has received criticism from both sides of the political spectrum, with conservatives and liberals claiming bias. This is because some facts that the site claims to have been checked could not possibly have been examined. However, PolitiFact has received praise for some of its efforts. With the motto “Sorting out the truth in politics,” and its mandate to employ ethical, strict journalistic standards, PolitiFact’s fact finders attempt to confirm the accuracy of discourse that impacts daily civic life.

Polling

A straw poll is an informal survey of attitudes about an issue, candidate, or event that does not have binding consequences in the arena in which it takes place. The first political poll, which was a straw poll, was introduced during the election of 1824 in Pennsylvania. This poll predicted that Andrew Jackson would win over John Quincy Adams, and Jackson did win the popular vote but lost the electoral college (which was not the object of the survey).

Over the next century, the process of data collection evolved into direct-mail solicitations through the magazine of the day, *Literary Digest*, which contacted millions of potential voters as its sample and successfully offered predictions on presidential elections from 1916 through 1932. In 1936, *Literary Digest* opted to base its sample on motor vehicle registrations and phone numbers, which biased its sample, and led to the prediction that the more affluent candidate, Alf Landon, would be the next president. Of course, Franklin Delano Roosevelt was re-elected for the second time, and due to its errors, *Literary Digest* lost credibility and soon went out of business.

Instead of collecting data from millions of people, as had been the practice by *Literary Digest*, George Gallup and Elmo Roper used representative sampling methods of fewer people to predict the outcome of the 1936, 1940, and 1944 elections. Gallup and Roper began using the modern scientific approach to polling by implementing a probability sampling technique and a margin of error. In 1948, Gallup, along with other pollsters, predicted that Thomas Dewey would win

the presidency. Yet, Truman won re-election, and the polling error is reflected in the famous photograph of Harry Truman holding the *Chicago Tribune* newspaper with the headline "Dewey Defeats Truman." This catastrophic effort was explained by embarrassed pollsters as "late deciders" breaking for the president.

Since the 1950s, polling has become an important part of the political campaign process for a variety of reasons, including the media's penchant for horse-race-oriented campaign stories to entice and keep market share, as well as campaigns' attempts to formulate messages that reflect a candidate's strategy in winning the election or success in a public policy initiative. Polling has proliferated in recent times. In 1972, there was one national presidential poll during the last three weeks of the election; in 2008, there were 24.

Why Use Polling?

Polling is utilized in politics to gauge the public's attitude toward a person or issue, and to learn what message could persuade a particular type of voter to support a particular person or issue. Polls can measure candidate viability through the ballot test question, and evaluate the effectiveness of a particular communication strategy. For instance, polling allows a representative sample of 1,000 people to share their opinions on a candidate or issue, thereby providing the researcher the ability to extrapolate such findings to the overall population.

Polling provides data on key segments of constituents of the population's attitudes toward a particular issue, in contrast to the overall population. Standpoint theory affirms that it is problematic to truly understand someone else's perspective of the world because every person is shaped by multiple factors and individual experiences. Polling provides a vehicle to understand trends, similarities, and the differences of subgroups within the general population.

Data Collection

There have been many changes in collection methods of data over the last 100 years. For instance, the straw poll, which was popular in the 19th century, is now viewed more as a fundraising gimmick, rather than a legitimate and accurate measurement of public opinion. For example,

The Ames, Iowa, straw poll has been important to the Republican Party since 1980. Fred Karger speaks at the Iowa State Fair in Des Moines, Iowa, prior to the straw poll. Karger was a Republican candidate for the 2012 presidential election.

the Ames, Iowa, straw poll has been used by the Republican Party since 1980, but has accurately predicted the eventual nominee only twice (1996 and 2000).

Direct mail and face-to-face interviews for data collection were the most popular techniques used in the early 20th century. Direct mail continued to be popular into the late 1980s. Yet, the increased cost of postage and the decrease in responses adversely impacted the reliability of this data collection method. The face-to-face interview also became too costly, and was hampered by potential interviewer bias. In response, the modern polling industry adopted the telephone as its favored means of data collection.

Live-operator phone calls continue to be the standard practice because they allow access to most of the population and there is no limit on what sample of the population one can access via cell phones. A total of 11 of the 22 national polling firms use this telephone method.

For the last decade, telephone data collection has evolved with voice over Internet protocol (VOIP) and interactive voice recognition (IVR) software, known as auto calls or robocalls. This system of data collection allows for a prerecorded

message to be played to all recipients. Recipients respond with keypads to enter their choices. According to Nate Silver, the most accurate pollster in 2008 and 2010 was Scott Rasmussen, and in 2012 Public Policy Polling; both use IVR data collection.

One explanation for the accuracy of IVR data collection is the trend for increased automation in people's day-to-day lives, including touch systems for customer service, self-banking, and even self-checkout at stores. However, there are challenges as IVR may lose its legitimacy in data collection, given that the FCC has made it illegal to call cell phones, which limits the sampling frame. Internet data collection is growing in popularity with the ability to ask longer questions and have a representative sample. Firms like Ipsos/Reuters and Google Consumer Surveys were remarkable successes in 2012.

Aggregate Polling

Known as "the poll of polls," aggregate polling has been around since 2000. The distinguishing characteristic of aggregate polling is that statisticians do not actually conduct any polls themselves but rather collect polls and use a weighting system to predict the outcomes of races. Critics argue that aggregate polling compares apples with oranges, as each poll has different margins of error and different data collection processes. Nonetheless, proponents argue that the reliability of results as accurate predictors proves the validity of the method. Real Clear Politics was the first to introduce this method to the mainstream, and aggregate polling is now very popular in the media, as is evidenced by the *Huffington Post* and the *New York Times*' blog by Nate Silver, www.fivethirtyeight.com.

Web Analytics

Today's pollsters are opting for noninvasive ways of measuring attitudes as a means of countering the Hawthorne effect, which suggests that the act of observation will affect behavior. Web analytics examines the dynamics of individuals on the Web. As people surf the Web, data is constantly collected about which pages a person visits, how long he or she stays on a page, and how many comments are generated by a story or quote. Some analytics include the number of "likes" or

“friends” on Facebook, the number of followers on Twitter, or the number of views on YouTube. One critical concern is that social network sites can be artificial or have purposefully inflated counts due to advertising.

Types of Polling

Cross-sectional polls are the most common type of polling used in political campaigns. These are snapshots-in-time polls, where a poll is conducted in a few days or less. Such polls are also called benchmark polls and brushfire polls. These types of polls are limited in value because there is only one result to analyze, as opposed to longitudinal studies.

Tracking polls are popular in determining the effects of how messages are received by voters. Tracking polls are conducted through a series of shorter polls over the course of days, weeks, or even years.

Overnight and flash polls are typically used to learn the effects of a particular event, such as a debate, or if an advertisement or direct mail piece is having the intended effects. These polls are done in one night, and have a few questions that directly examine a communication phenomenon.

Bellwether polls use a sampling technique that identifies a region or city/town of a state that closely reflects the voting trends of the entire state. This region is polled and the results are generalized to the overall population.

Push polling is a message strategy technique that is designed to resemble a scientific poll. The purpose of push polling is not to measure the attitudes or feelings of a potential voter, but rather to persuade a voter through the use of leading questions.

Exit polls are conducted the day of an election; voters are asked to tell interviewers who they voted for and about their demographics. The U.S. Constitution calls for a secret ballot, and in order to learn the demographics of voter support for a particular candidate or issues on Election Day, pollsters will visit various voting locations to interview voters after they have cast their votes.

Polling Effects

There are multiple theories on the effects of polls on society, but the extent and magnitude of such effects is up for debate. Some advocate that a poll

early in the campaign, that shows a candidate winning will create a bandwagon effect as people want to be associated with a winner, and will support a candidate early in the process, thereby limiting the ability for a challenger to persuade voters.

In contrast to the bandwagon phenomenon is the underdog effect, based on the notion that people root for the underdog, as witnessed by the David versus Goliath narrative. When a poll shows a candidate losing, this theory postulates that people will rally around the candidate and support him or her in opposition to the presumptive winner.

Immediacy theory argues that people are intensely interested in the results of elections, and that instead of waiting for Election Day to count the votes, there is a need to know who is winning at any given point. As a result, the popularity of polling has increased. This horse race phenomenon provides pundits something to talk about during the campaign dependent upon the polling results. However, LaPiere's studies of the 1930s that found that attitudes do not necessarily reflect behavior, and several indicators, such as favorable opinion, may not result in an actual vote.

Question Design

Two key concepts regarding polling are validity and reliability. Validity asks, “Are we studying what we claim to be studying?” and reliability looks at the consistency of the instrument used to collect the data in terms of its ability to measure the same thing the same way each time. Such factors as the time of day a survey is administered, the day of the week, and the weather can influence the results and lower the reliability of data.

Basic survey format includes a screening question, name recognition questions, followed by ballot tests, then issue and message strategy questions, and finally demographic questions.

Screening questions are used to qualify a person to participate in the survey. Most polls for electoral politics will ask if the person is registered or likely to vote in order to qualify for the survey. Yet there is a caveat, which will be discussed subsequently, in the “likely voter model.”

Name recognition is a product of favorability questions, where respondents are asked if they have a positive opinion, negative opinion, no

opinion, or have never heard of the candidate in question.

Ballot test questions are asked after the name recognition questions, so as to not influence the former. These questions focus on who voters are going to vote for. Most pollsters write and order the responses based on what the voter will see on the ballot on Election Day. Issue and message strategy questions focus on identifying what issues are most important to voters. Demographic questions focus on age, party affiliation, gender, socioeconomic status, education level, home ownership, marital status, race, ethnicity, and children, and so on. Open-ended questions allow interviewers to freely choose their answers, but can be difficult to analyze because they need to be categorized and coded. Most polls use forced choice question design.

Polling can be used as part of a media audit to determine where voters get their news, what programs they watch, or what other sources they use throughout the day in order to target messages to these individuals.

Wording of questions can bias the validity of a poll. For example, using loaded words such as if a person “supports the killing of babies” would likely result in an answer of “no,” but the question of whether someone “supports abortion” could elicit a “yes” response. Other examples include double-barreled questions in which two questions are asked at once. Leading questions are characterized by an assertion that predisposes the recipient to a particular response.

Sampling Methods

A sample is a subset of the population. Probability sampling refers to the opportunity for everyone in a population to have an equal opportunity to be chosen. Since political polling is protected as political speech, the “do not call list” does not apply and all phone numbers can be dialed. The exception is that if one is using an automated data collection method, one is not allowed to call cell phones.

The two most common types of probability sampling employed by pollsters are random digit dial (RDD), and using a random sample from a list of registered voters. RDD is a probability sampling method that randomly generates telephone numbers by using area codes, followed by

three-digit local exchange code, and then a random assignment of the last four digits. An important caveat with this technique is if one generate one’s own RDD list, one must make sure to eliminate any emergency numbers, including police stations and hospitals.

Registered voter lists can be acquired from the Secretary of State’s offices normally for free, or for a nominal cost. However, many private vendors provide this data to candidates and campaigns as well. A typical random sample provided by a vendor costs \$350 to \$500 depending on size and any stratification requests.

Data Analysis

Polls are analyzed through top-line results (referred to as frequencies or marginal), which are the percentage of responses given for each answer to each question. Most pollsters only use cross tabulations as further analysis, and do not employ advanced statistical testing such as Chi Square, Anova’s, t-test, correlation, and regression analysis.

Before results are published, most pollsters will determine if the sample that answered the poll is representative of the entire population, based on a set of parameters such as age, gender, and party affiliation. If the sample is not representative, then the pollster will use a system of weighing prior to analyzing the results.

Weighing is the process of assigning more value to one demographic and less value to another. For example, if a sample has 100 respondents, and 70 were women and 30 were males, but it is known from voter registration numbers that gender is split 50/50, then one would devalue the results of women by dividing 70 by 1.4 and multiplying men 30×1.67 to create a representative sample of 50/50.

Using multiple demographics is more complex and there is no universal, agreed-upon weighing principle used by all pollsters. Yet, the general rule is to either collect a large enough sample in order to eliminate enough respondents to match the parameters set by the demographics, or after each weighing of one demographic, making adjustment in other demographics.

Perhaps the most important criteria for weighing is party affiliation, and some firms use a likely voter model (LVM), which accounts for the

variance in survey results for any given race. Pollsters use a variety of techniques to determine the LVM of any given election, including exit polling and party registration numbers. Some pollsters do not weigh their results, claiming that the randomness of the sample is what makes the results representative of the overall population.

Margin of Error

Margin of error (MoE) is a statistic used to determine how much sampling error is contained in the results of a survey. It is a standardized value primarily related to sample size, assuming a random sample research design. It quantifies the amount of unavoidable error that is built into the sampling process, since there can never be a 100 percent match between a sample and the population from which it is drawn.

A MoE is calculated based on the size of the sample, and to a certain degree, the size of the overall population. Simply put, in a random sampling design, the more people who answer the survey, the lower the MoE. Sample error is then used in further calculations, including the linked numbers' "confidence level and confidence interval." Once calculated, the numerical value of the margin of error is then applied to the "average" or mean response to a question, first as an addition, then as a subtracted number (since one does not know if the error is "too high" or "too low" relative to the unknown true value), resulting in a range of percentage values along which the accurate measurement can be presumed to lie. This is called the "confidence interval." "Confidence level," a related term, refers to the relative proportion of all possible cases that any particular confidence interval can be expected to describe, using the mean value as a point of reference and expanding in both directions (positive and negative valences) to cover increasingly large areas of the Bell Curve that describes the total population.

Social science research typically uses a 95 percent confidence level, which in clear language means that it calculates the range of values revealed in the survey, and along which the "real" value (in the population) is presumed to occur, to describe 95 percent of all possible cases. This is also frequently expressed as being "95 percent confident" in one's results, or as being confident that one's results are accurate "95 times out of

a 100," although such colloquial interpretations can sometimes run the danger of sliding toward over-simplification.

Challenges for the Future

Equifinality suggests that there are multiple ways to reach a desired outcome, and this certainly applies to polling. Methods of data collection and analysis have continued to evolve from the days of the first straw poll conducted during the 1824 presidential election, and the challenges presented by the *Literary Digest* approach to public opinion. For example, over the last decade, modifications in techniques have changed to ensure a representative sample, with younger people opting for cell phones and abandoning landlines. In order to reach subgroups of the population, multiple methods of data collection will become more prominent in the future, including the use of Web analytics and the Internet.

An example of how different forms of data collection can lead to bias responses is a study conducted by Pew Research Center (2010), which suggests that people who answer the polls on landlines are biased toward conservative values by about 5 percent versus those who answer via cell phones. Those successful in gauging public opinion via polling will remain vigilant and cognizant of such changes within the public and its means and manner of decision making. To do so increases the likelihood that polling predictions mirror reality, which is the bottom line in the credibility of any pollster.

Pornography, Revenge

The term *revenge pornography*, or *involuntary pornography*, refers to Web sites where users post sexually explicit images of individuals, primarily women, without their consent, often along with their full legal names and detailed contact information, including Facebook profiles or other social media identities, so that third parties may harass them. It also refers to posting this type of sexually explicit material on other people's online and social media sites in order to give the impression that the owners of those sites consume pornographic material, when in fact this may not be the case. Typical "revengers" are the depicted individuals' ex-partners. Nude images, however, may also be posted by hackers. Apart from nude images and contact information, users may also post false information that creates a negative image of the person who is subjected to further humiliation. Revenge pornography Web sites subject individuals to severe emotional injury, pecuniary loss if they lose their job, and a significant likelihood of being stalked and harassed in cyberspace and real life.

Misconduct

Revenge pornography Web sites refer to the generic group of social media. Similar to social networks, Internet forums, and blogs, revenge pornography Web sites offer a site for interactions among people in which they create, share,

and exchange information and ideas. Just as YouTube or Facebook host other people's images and videos, revenge pornography sites enable users to post nude images and videos for vindictive purposes, whereby the person submitting information accepts full responsibility for uploading it.

Although revenge pornography Web sites may feature private information of men and couples, women's images are prevalent and constitute the majority of profiles. Sexually explicit images are often acquired by victims' ex-partners in the course of the romantic relationship. They may be obtained with the consent of the woman when she, for instance, sends intimate "sext" messages, sexually explicit text/video messages via a cell phone or social media networks, to her partner. Alternatively, nude photos may be attained by hackers clandestinely from victims' PCs, social media profiles, and cell phones. Revenge pornography sites are large repositories for amateur pornography and online discussion platforms where users can share opinions about the contents. They also serve as easy sources of private information, including revenge subjects' names and city of residence, as well as screen shots of their social media pages.

Despite the sexually explicit content of revenge pornography sites, revenge pornography should not be confused with conventional forms of pornography. Traditional pornographic materials are produced by consenting adults. Revenge pornography is nonconsensual pornography, whereby those individuals whose nude images are posed online are denied the rights to consent to be used as sex objects by Web site users. The very purpose of revenge pornography is to allow users of the Internet to post, exchange, and comment on nude images in order to shame, humiliate, and destroy the lives and reputations of hand-picked targets.

Although defenders of revenge pornography argue that the information they use is already available online through multiple sources, critics counter that these Web sites deliver private information while making women, without their express consent, subjects to sexual harassment and sexual fixation for (cyber-)stalkers and trolls. Revenge pornography sites allow posting comments that are cynical and sarcastic remarks on intimate photos. Most of them mean to shame those who are featured for their provocative

content. Because revenge pornography sites reveal detailed private information about victims, stalkers are provided with sufficient information to find victims, follow them, and research them through their use of social media profiles, work Web sites, forums, and online directories. Stalking via smartphones, social networking Web sites and in real life may present risks to the victims' emotional and physical health.

Allegations and Lawsuits

Intrusion into an ordinary person's private sexual sphere may generate considerable profits. Promising fast and easy revenues, revenge pornographers have demonstrated persistence and creativity, filling in a gap in the amateur pornography market.

Revenge pornography seems to have first come to the public eye with the launch of the site *IsAnyoneUP.com* in 2010. Founded by Hunter Moore, *IsAnyoneUP.com* was the materialization of an idea that came from a woman who continuously sent Moore sexually explicit shots. Moore created a blog for his collection of images, which was quickly expanded to include other nude pictures sent by Internet users. Revenge-seeking users rapidly upgraded Moore's unexceptional blog into a well-known online database of nude images and personal information.

IsAnyoneUP.com garnered over 30 million page views a month, and earned up to \$10,000 a month until Moore decided to shut it down on April 19, 2012, following mounting public pressure. Because the site attracted a great deal of condemnatory attention, much of which was related to child pornography, defamation, and privacy invasion, Moore was subjected to investigation by the Federal Bureau of Investigation (FBI). He faced numerous lawsuits, such as one by James McGibney, in which Moore was found guilty of defamation and was fined \$250,000 in damages.

In February 2013, John S. Morgan sued and shut down another revenge pornography site, *www.Texxxan.com*, citing copyright infringement under Texas state law. The lawsuit on behalf of more than two dozen local women claimed that the site was designed to cause humiliation and emotional distress. The lawsuit also alleged invasion of privacy, gross negligence, emotional distress, and civil conspiracy on the part of the Web site operator. *CajunWins.com*

and *DirtyBlast.com* disappeared when *Texxxan.com* went offline as a result of the pending lawsuit. *Pinkmeth.com*, maintained by anonymous individuals, is still in operation with a pending lawsuit in Denton County Court, Texas, by Shelby Conklin. She claims punitive damages of \$1 million from *Pinkmeth.com* for intrusion on seclusion, public disclosure of private facts, appropriation of her name and likeness, and intentional infliction of emotional distress.

Criminalization and Legal Remedies

Revenge pornography has been subject to much controversy. Law enforcement officers and prosecutors face increased pressure to work with cases of nonconsensual pornography. Victimized individuals have resorted to suing site owners or those associated with revenge pornography for hosting nude images displayed online. Revenge pornographers make money by posting nude images and have little incentive to create policies that make it easy for victims to remove the submitted photos. More refined legislation is necessary to more narrowly define the conditions under which the victims of revenge pornography are protected. Such legislative maneuverings are very likely to be pushed back by companies and organizations that seek to keep content restrictions on the Internet as minimal as possible.

Revenge pornography sites, as much as other social media Web sites, enjoy certain protections from liability for the contents posted by users in the United States under the Communications Decency Act (CDA) of 1996. Section 230 of the CDA immunizes Web sites from liability resulting from the publication of information provided by others. As long as published material is not illegal to post (e.g., child pornography or copyrighted material), Section 230 provides immunity for Internet service providers, including blogs and Web sites, that publish information provided by third parties. Protections under the CDA, however, are not without limitations. Section 230 does not protect the third parties who post illicit content on the Internet. Administrators of revenge pornography Web sites could face liability for facilitating the violation of Section 230.

Given the proliferation of revenge pornography in a legal environment that makes it very difficult to criminalize legal pornography, a series of lawsuits

against revenge pornography Web sites instigated the launch of a public campaign against involuntary pornography supported by petitions for both state and federal laws in the United States. Petitioners urge fighting revenge pornographers who post intimate images without permission. They call for the amendment of cyberstalking laws and enactment of an invasion of privacy statute that would criminalize revenge pornography.

Florida is the first state in the United States to attempt to take an action against revenge pornography. House Bill 787, effective October 2013, makes posting revenge pornography a felony punishable by up to five years in prison and a \$5,000 fine. It made it a third-degree felony for a person to knowingly use a computer, or other device capable of electronic data transmission or distribution, to transmit or post to a Web site or any other social networking service, or cause to be posted to a Web site or any other social networking service any photograph or video of an individual that depicts nudity and contains the depicted individual's personal information, or counterfeit or fictitious information purporting to be such personal information, without first obtaining the depicted person's written consent, unless the victim was photographed or videotaped in public.

Hacktivists Against Revenge Porn

The owners of revenge porn sites have been under attack by online advocacy groups. Anonymous, a group of unidentified Internet users engaged in a controversial online resistance movement on a number of sociopolitical matters, declared war on Hunter Moore in 2012. Although best known for targeting corporate Web sites, Anonymous's operations were to "make a real difference in the lives of hundreds of bullied teenagers and protect them from real harm such as rape or stalking."

In Operation Hunt Hunter, Anonymous hacked and distributed Moore's personal information, including date of birth, address, phone number, parents' names, social networking details, internet protocol (IP) addresses, and a list of pending lawsuits. In another operation, Operation Darknet, Anonymous hacked into and stole users' e-mails and passwords from several child pornography Web sites, later releasing them to the public. Despite the pronounced antipornography

agenda, Anonymous attacked YouTube with pornographic film clips disguised with tags of teen idol musicians to avoid detection and increase their chance of exposure across the site.

Evaluations of Anonymous's activities thus vary. On one hand, Anonymous's philosophy and modus operandi have received wide public support. On the other hand, hacking activities have been criticized for making Hunter Moore a victim, as is anyone else who is picked on by hackers promoting a particular set of sociopolitical ideals.

Portman, Rob

Rob Portman, the junior senator from Ohio, has been considered twice as a potential vice presidential candidate and often serves as a nemesis for Republican candidates during debate practice. His relative low profile belies his conservative policies and accomplishments. Democratic Senate Budget Committee Chairman Kent Conrad has said, "He is a person of credibility and decency that commanded respect on both sides of the aisle." Former President George W. Bush called him a "good friend, a decent man, and a skilled

negotiator.” These two statements sum up Portman’s character.

Portman was born in Cincinnati, Ohio, on December 19, 1955, to Joan and William C. Portman II. When he was young, his father borrowed money to start the Portman Equipment Company, a forklift dealership. The company grew from a small business in which Portman, his siblings, and mother all worked, to a sizeable and successful enterprise that employed more than 300 workers.

Portman graduated from the Cincinnati Country Day School in 1974, and Dartmouth College in 1979, where he earned a Bachelor of Arts. In 1984, Portman graduated from the University of Michigan Law School. In July 1986, Portman married the former Jane Dudley, who worked as an aide to then Democratic Congressman Tom Daschle. The Portmans have three children: Jed, Will, and Sally.

Portman and his siblings own the Golden Lamb Restaurant and Inn in Lebanon, Ohio. The property has been in his family since 1926, and has a reputation for being haunted. Along with the inn, Portman’s interest in history runs deep. He penned his only book to date, with coauthor Cheryl Bauer, about an Ohio Shaker Village founded in 1805. The book, *Wisdom’s Paradise: The Forgotten Shakers of Union Village*, was published in 2004.

Outside of politics, Portman enjoys physical challenges. He bikes, canoes, and kayaks. He has kayaked two major Chinese rivers, and the entire Rio Grande.

Legal Career

After graduating from law school, Portman moved to Washington, D.C., to work for the law firm Patton Boggs, where he practiced trade law and lobbied on behalf of clients. From there, he moved back home to Cincinnati and joined the law firm Graydon Head & Ritchie, where he practiced business and international law.

It was not long before Portman returned to Washington. In 1989, he joined the White House staff of President George H. W. Bush as an associate counsel. He quickly moved up to become deputy assistant, and then director of the White House Office of Legislative Affairs, where he served as the president’s chief lobbyist on Capitol Hill until 1991.

In 2007, after another stint in the White House, this time serving under President George W. Bush, Portman returned home to Cincinnati and legal practice. He joined the law firm of Squire Sanders as part of the firm’s transactional and international trade practice, where he practiced until winning the Senate seat that was vacated by the retirement of George V. Voinovich in 2010.

presidential Appointments

Shortly after winning a second term in office, President George W. Bush nominated Portman to become the U.S. Trade Representative. He quickly won Senate confirmation and was sworn in on May 17, 2005. Upon taking office, Portman became the first sitting congressman in history to hold the post. With trade law in his background and years on Capitol Hill working on trade issues, Portman quickly advanced and successfully gained congressional approval for trade deals with Bahrain, Peru, Oman, and Colombia.

Portman successfully navigated approval for the Central American Free Trade Agreement (CAFTA) after a bruising battle. Portman’s power of persuasion served him well during intense congressional debates. The Senate eventually passed the measure with only a nine-vote margin. However, victory in the house was even more difficult. The House passed the bill with only a two-vote margin, 217–215, on July 28, 2005.

Following his success on CAFTA, President Bush called on Portman again to take on a tough assignment. On April 18, 2006, Bush nominated Portman to become director of the Office of Management and Budget (OMB). The Senate unanimously confirmed Portman on May 26, 2006. Portman stayed in the position for only one year. In a later interview with the *Hill*, he lamented, “I was frustrated when I was there about some spending issues—specifically, as you know, I wanted to offer a balanced budget over five years, and a lot of people didn’t.” However, Portman’s skill for gaining consensus helped him persuade Bush to submit his first plan to balance the budget and eliminate the deficit by 2012. Even though he was “frustrated,” Portman remained loyal to Bush.

Congressional Career

With the encouragement of his friend Congressman John Boehner (R-OH), Portman decided to

run for Congress in 1993. He won the special election to fill a spot vacated by his friend and mentor Bill Gradison. Portman had worked on Gradison's earlier congressional campaign for the seat he would eventually win, and hold for 12 years.

From 1993 to 2005, Portman represented the 2nd Congressional District of Ohio in the U.S. House of Representatives. He won seven consecutive congressional elections with over 70 percent of the vote. Portman worked on a wide range of issues and championed many diverse causes. For example, he worked to gain passage of a ban on unfunded mandates, supported welfare reform, passed a measure to eliminate capital gains taxes on home sales, and cosponsored a bill to swap Costa Rican debt for preservation of tropical forests. In 2004, he teamed up with Louis Stokes, then a Cleveland-area Democratic congressman, to pass a bill that would create the

National Underground Railroad Freedom Center in Cincinnati.

Over the course of his House career and tenure in the executive branch, Portman was known for his willingness to work with Democrats to ensure important legislation was enacted, all the while maintaining his devotion to conservative ideals. While in the House, Portman voted with the Republican majority 90 percent of the time, and garnered consistently high approval ratings from conservative organizations such as the National Right to Life Committee, National Taxpayer's Union, Americans for Tax Reform, and the Christian Coalition of America.

When Ohio Senator George V. Voinovich announced his planned retirement from the Senate, Portman immediately formed a team to seek the seat. Portman won a decisive victory in 2010 by a margin of 57 to 39 percent of the vote. Since joining the Senate, he returned to the traditional issues he has focused on for much of his career—the country's debt and economic recovery.

In August 2011, Senate Minority Leader Mitch McConnell (R-KY) appointed Portman to the high-profile Joint Select Committee on Deficit Reduction. This bipartisan panel was created to recommend ways to reduce the federal budget deficit by \$1.5 trillion over 10 years. When the effort bogged down, Portman left disappointed, telling the *Columbus Dispatch*, "I am very sad about this process not succeeding because it was a unique opportunity to both address the fiscal crisis and give the economy a shot in the arm."

In the Senate, Portman serves on the Senate Committee on the Budget and the Senate Armed Services Committee, where he is the ranking Republican on the Emerging Threats and Capabilities Subcommittee, a member of the Subcommittee on Readiness and Management Support, and a member of the Subcommittee on Strategic Forces. He also serves on the Senate Energy and Natural Resources Committee, where he is a member of the Subcommittee on Energy, the Subcommittee on National Parks, and the Senate Committee on Homeland Security and Governmental Affairs. Portman is also a member of the Senate Committee on Homeland Security and Governmental Affairs, serving as a member of the Subcommittee on Federal Financial Management, Government Information, Federal Services, and

U.S. Senator Rob Portman (left) pins the Silver Star medal on Sergeant Thomas Gdovin (right) on November 8, 2011. Gdovin was awarded the medal for risking his life to save a wounded soldier while under enemy fire during the Vietnam War in 1968.

International Security, and as the ranking Republican on the Ad Hoc Subcommittee on Contracting Oversight.

Communication and Social Media

While Portman has been an integral part of the governance of the country for more than 20 years, his name is not as well known to the public outside of his congressional district. He has been quietly and intensely working inside the “Beltway” to pass legislation, but not working the media or social media. While he is on multiple platforms of social media, he is a relative newcomer.

Portman’s Senate Web site links to the social media platforms on which he is active. These platforms include: Flickr, Twitter, Facebook, and YouTube. Portman also posts audio files to his online newsroom. These files are often public service announcements or discussions on important issues. There are no favorite videos posted on his YouTube channel; instead, he posts certain videos directly to his Senate Web site. Weekly columns are used like blog posts to his Web site and cover a range of topics and issues.

There are more than 200 photos posted to Portman’s Flickr photo-sharing account. The photos vary from a meeting with police officers in Lima, Ohio, to a picture of Portman looking out over Paktika Province on a visit to Afghanistan. The majority of the pictures he shares are of folks in his native state of Ohio—constituents, business owners, and veterans. Sprinkled throughout is the occasional head of state or foreign trade representative next to Brutus the Buckeye, Ohio State University’s mascot.

Portman also utilizes Twitter to connect with constituents. In just over a year, he gathered nearly 23,000 followers. His tweets are more personal in nature, such as congratulating college sports teams, tweeting pictures of himself and a teammate winning a kayak contest, and asking constituents for movie recommendations. However, he does not shy away from tweeting about disagreements with Democratic policies or supporting Republican candidates for office. He also will retweet articles and information that he wants to share with his followers. His communication style is casual and unassuming. The Senator does not tweet as often as other members, but he uses the platform nearly every day.

Portman’s Facebook page dates back to February 2011, when he used his first post to announce that he was “up and running” on social media and inviting constituents to communicate with his office via Facebook, Twitter, and YouTube. He quickly paid tribute to his mentor and friend President George H. W. Bush by posting an article and congratulating him on being awarded the presidential Medal of Freedom. He uses Facebook often, sometimes posting more than once a day with updates on votes, links to his YouTube channel for floor speeches, pictures of Ohioans, and even a proud post showcasing a stint as a guest blogger for the Heritage Foundation, a conservative think tank.

In a little more than a year on YouTube, the Senator had more than 54,000 views of only 166 videos. The Senator also links to his Google+ account from his YouTube channel, inviting viewers to “hangout” with other Portman friends. Unlike his approach on Twitter and Facebook, Portman’s videos are decidedly more policy heavy and more partisan in nature. Videos showcase the Senator testifying on specific bills, criticizing Democratic policies on national news shows and video responses to questions from his Twitter and Facebook accounts about health care reform.

The Senator maintains only a shell campaign Web site at robportman.com when he is not actively campaigning. While visitors can sign up to receive e-newsletters, the blog, newsroom, and other functions are not active when the campaign is not active.

Portman uses his Senate Web site and social media effectively as tools to provide information to constituents. While he is not prolific, his communication seems genuine and appears to reflect his overall communications style—understated, but clear. As is his style, there are very few vanity pictures, posts, or videos. Instead, the information Portman provides reflects back to the issues he has championed and that voters in Ohio want to know and follow.

Poverty

Poverty is the lack of sufficient resources to meet one's basic needs such as food, shelter, and clothing. In the United States, this is measured by a theoretical poverty threshold calculated by the U.S. Census Bureau, while eligibility for welfare programs and benefits is measured by poverty guidelines established by the U.S. Department of Health and Human Services.

Poverty is relative to the cost and style of living in a particular community. The level of income established as "poverty" in the United States can provide a very comfortable lifestyle in other parts of the world. A 2011 United Nations (UN) study,

"The Global Social Crisis," warns that between 47 million and 84 million more people fell into or were trapped in extreme poverty because of the global financial and economic crisis. The World Bank suggests that what makes people poor is not just low income level, but also being illiterate, having high health risks, and living in squalid conditions. This creates a profound deprivation in wellbeing.

Another approach to understanding poverty is the capability approach of Amartya Sen, the 1998 Nobel Prize winner for Economics. This model extends the definition of poverty to include vulnerability to risk, lack of voice in society, and powerlessness. This builds on the notion of wellbeing to develop an awareness that poor people need the capability to function in society. Capabilities included both the access to meet basic needs (food, clothing, and shelter) but also access to education, health care, security from violence and other risks, and political empowerment and equality.

Closely related to the notion of poverty is inequality, which highlights the gaps between the rich and poor. These gaps include differences in any of the indicators of wellbeing and the distribution of economic, political, and social opportunities. By definition, those who are poor or live in poverty have resource limitations and a resulting lack of access to social media; in many cases, the lack of social status brings many to feel politically disempowered, despite their equivalent right to vote, if they qualify.

Access to and Use of Social Media by the Poor

Social media and the Internet have become valuable sources of information about current events throughout the world. Informal social networks using blogging and social media sites as well as the traditional news media, both print and television, use the Internet to disseminate information. As might be expected, many of the extremely poor do not necessarily have access to these resources, which require the use of computer and media equipment and a service provider. Depending on their location, some individuals may have access through public facilities such as libraries, schools, and Internet cafes, which provide low-cost access.

Public and nongovernmental programs have been designed to provide low-cost Internet access

and equipment to low-income individuals. Certain municipalities have developed public Internet access, which is free. Comcast, an American Internet provider, offers low-cost Internet service and inexpensive computers to low-income households with children who qualify for and receive free or reduced-price school lunches through the National School Lunch Program. One Laptop per Child has developed rugged, low-cost, low-power connected laptops that are distributed in developing countries.

Internet access has increased for individuals with limited incomes via low-cost cell phones. Cell phone communication has been a powerful tool in mobilizing individuals in political protests such as the Arab Spring and Occupy Movements. Yet, in some developing countries where social media access is limited or nonexistent, even these tools are not available to those who wish to make change. This access and economic imbalance can result in global awareness of events of immediate concern to populations that do not have the technology and social media access with which to know what is happening that directly impacts their lives.

Poverty as Portrayed in Social Media

There are multiple ways of looking at the relationship between poverty and social media. One way is by determining how poverty is portrayed in social media. A brief search of Facebook for the word *poverty* produces many international groups and pages. Most of these are maintained by nongovernmental organizations focused on providing awareness education and dedicated to the eradication of poverty. Posted updates about their projects and activities inform viewers who are asked to “like” their pages and share them with Facebook friends. When an individual “likes” an organization’s Facebook page, it will be displayed to everyone in their network, which costs nothing, and helps raise awareness about an issue like poverty.

Unfortunately, this may provide some individuals with a sense of contribution, when they have actually done very little. These tools allow one to say they care about the poor, but not to actually care for them. It has been suggested that this raised awareness may eventually lead to actual actions such as donations, volunteerism, participation in social protest activities, political activism, or influencing a career choice.

Using Social Media to Eradicate Poverty

Many traditional organizations maintain Web sites to advertise their activities and solicit funds and support. These sites now contain tools to allow viewers to easily post to social media sites including Facebook, Twitter, YouTube, Pinterest, Tumblr, and others.

Numerous nongovernmental organizations have developed social media campaigns to help in their missions to eradicate poverty and influence political processes. Many combine educational resources, social media, and appeals for donations to reach these goals. A few examples can illustrate their potential and demonstrated effectiveness.

The World Bank is an international development cooperative of 188 countries that works with governments in developing countries to reduce poverty by providing money and technical expertise. It maintains a large Web site with research papers, data, and educational resources. Its social media strategy includes offering multiple mobile applications, over 30 blogs (<http://blogs.worldbank.org/blogs>) and links to the major social media networks (<http://live.worldbank.org/connect>).

In 2011, the UN brought together social media experts to discuss strategies for fighting poverty. At the time, they estimated that a total of 5 billion mobile phones exist worldwide through which many in developing countries access social media. For the 2012 International Day for the Eradication of Poverty, the UN established a one-day social media action to raise awareness about the progress made and the challenges that remain in the fight against poverty. Individuals were asked to donate their Facebook and Twitter profiles to send Poverty Day messages. The MyWorld Web site (<http://www.endpoverty2015.org>) was developed to maintain a social media presence to support citizen participation in achieving the UN’s Millennium Development Goals.

Cofounded by Bono in 2002, ONE (<http://www.one.org>) is a grassroots organization committed to the eradication of extreme poverty and HIV/AIDS. Using bright graphics, videos, and colorful text, the Web site is linked to the major social media networks. Links to encourage participation in the political process are provided for petitions to elected officials in support of legislation and public policy. Funds are raised through

online store sales of the classic white silicone ONE bracelet.

Worldvision is a Christian organization that uses the adopt-a-child model to make changes in poor communities throughout the world. While its official Web page lacks the bells and whistles of social media, one of its educational projects, 30 Hour Famine, educates students about famine and provides a group simulation game that asks participants to fast for 30 hours. This project site (<http://www.30hourfamine.org/learn-about-the-famine/>) includes educational information and projects, social media links, blogs, and directions for collecting and sending funds.

Recognizing the limited availability of technology in many underdeveloped countries, Text to Change (TTC) (<http://www.texttochange.org>) operates using simple cell phones. Founded in 2008, this organization creates innovative mobile solutions for technology access. TTC was the first of its kind in Africa to use mobile phones on a large

scale for social media purposes. This organization partners with other organizations (including the United Nations Children's Fund [UNICEF], and the U.S. Agency for International Development [USAID]) to provide mobile phone-based communication social networks dealing with development, education, and health projects.

While many of these organizations provide technical assistance and public education, the intended result of their social media campaigns is to develop public awareness about poverty and facilitate mobilization for political action.

Poverty, Politics, and Social Media

In recent years, social media have played a growing role in social movements and political change. Poverty, or the disparity between the haves and have-nots, has been at the root of many of these social movements. Economic issues play an important role in the current political atmosphere. The concept of the political economy highlights the

Sopheap Chak (center) a fellow in the Internet Freedom Fellows program funded by the U.S. Department of State and managed by the U.S. mission to the United Nations in Geneva, speaking at a Webcast on Internet Freedom in Geneva, Switzerland. Human rights activists from around the world convened in June 2012 to share experiences and lessons learned on the importance of a free Internet to the promotion of freedom of expression and assembly as fundamental human rights.

intimate interrelation of economic forces and the political process.

In the United States' 2008 presidential debate, CNN and YouTube collaborated to allow individuals to send in videos asking questions of the candidates. Many of the individuals posed questions about unemployment, taxes, home mortgages, and the recession. If not for the access through YouTube, they would not have had the opportunity to ask questions since they were not members of the political elite. It has been suggested that this advance in election politics is as significant as the impact of television on the political process was during the Kennedy–Nixon debates in 1960.

Throughout the world, several countries have forced political leaders to leave office, resulting in changed political control of their governments and the promise of access to economic resources. Many of these movements have used social media within their organizations to provide information to global news networks. When thousands of protesters took to the streets in Moldova, Iran, and Egypt, political forces changed the face of governments. Political and economic issues were implicit in these movements. It was not the wealthy who were protesting, but mostly struggling middle-class and poor citizens who felt a lack of access to needed resources. During the uprising in Iran, the U.S. State Department asked Twitter to postpone a scheduled maintenance shutdown because of the importance of this communication tool.

The Occupy Movement has spread worldwide, and while not specifically focused on poverty, it has drawn attention to the economic disparity between the 1 percent of the population, which holds most of the wealth in the world, and the other 99 percent, which while lacking resources, holds more political power through voting numbers. The recent American elections show that the Super Political Action Committees (PACs), funded by the extremely wealthy, were not able to override the will of the voters in favor of their candidates.

Conclusion

Internet access, social media, and economic issues will continue to influence political processes. Increasingly, many poorer individuals are gaining access to social media and education. They become informed about the world and will continue to use the tools available to them to influence

political processes and struggle for economic equality. The functionality and cost of smartphones allows more individuals to participate in social media campaigns. As costs come down and communication networks expand, those who are living in poverty and are currently disenfranchised will increasingly use social media to change political processes and alter their economic lives.

Predictive Analytics

The term *predictive analytics* broadly refers to various data-mining techniques that examine patterns and relationships using large and complex datasets for the purpose of making predictions of future trends and behaviors. While the term is typically used in conjunction with business marketing, predictive analytics are applicable to other fields such as epidemiology, health insurance, resource management, and finance. They are also increasingly applied in the political arena to better understand and predict voting behavior. Discovering meaningful patterns and associations based on past events and occurrences allows practitioners and organizations to better formulate future courses of action, generate more optimized planning and investing, and more effectively allocate resources.

Predictive analytics are inductive in nature. They are data driven and use a variety of analytical tools such as statistics, neural computing, robotics, computational mathematics, and artificial intelligence. The necessary first step in predictive analytics is data mining. During this step, all relationships (or correlations) are analyzed in the data to produce a predictive model. Predictive models may be developed with regression techniques (e.g., ordinary least squares) using conventional desktop statistical computer applications such as SPSS and SAS. Yet, other more advanced techniques such as neural network modeling can be used with less common applications such as JavaNNS and Emergent.

Because predictive analytics quite often employ large and complex datasets, or big data, this necessitates the use of specific database management and processing systems that are equipped to deal with such large data. To manage and analyze

big data, researchers may depend on massively parallel processing systems (MPP) that contain large numbers of processors.

In the context of social media research, users leave digital records in the form of comments, photos, or videos posted in blogs and various online social networking sites. These records contain metadata such as the date, time, and location of their creation. Indeed, the social media environment is appropriate for intelligence gathering in various disciplines, allowing researchers to acquire collective knowledge about current trends and events.

Predicting Election Outcomes

Predictive analytics have been used as a method for predicting the outcomes of elections in the United States. Most notably, these techniques have been used by Nate Silver, author of *FiveThirtyEight.com*, a blog created in 2008 that began publication as part of the *New York Times* in 2010. In his first attempt at applying predictive models in the arena of U.S. elections, Silver correctly predicted the outcome of the electoral college for 49 of the 50 states in the 2008 presidential election between Senators Barack Obama and John McCain. Silver went on to make predictions during the 2010 midterm election. However, he was less accurate in his predictions, with Republicans winning 65 seats in the House, 11 more seats than the mean gain of 54 seats that Silver's model projected. In the 2012 U.S. presidential election between President Obama and Governor Mitt Romney, Silver's predictive ability was reaffirmed. His model accurately predicted the electoral college for all 50 states. His model's accuracy in the 2012 election was further demonstrated when he predicted the popular vote to within half of a percentage point, and he predicted 31 of 33 Senate races.

Silver's development of predictive analytics is an outgrowth of the emphasis on the "horserace" in politics, a manner of framing the election in terms of which candidate is winning a particular race at a given point in time based upon who is ahead in political polls. Traditional political polling relies on research methods grounded in statistical sampling techniques in order to produce accurate samples of a specific voting population, such as at the state or national level. As Silver

has argued, the samples collected by polls are often inaccurate representations of the population. For example, pollsters often rely on land-line telephones to gather data. Young adults, who tend to vote Democratic, use mobile phones and cannot be reached by pollsters. Taking a different approach, Silver has produced statistical models that analyze an array of data points to arrive at a probability prediction that a candidate will win. Silver's methods rely on a number of factors, including historical performance of polls, past election outcomes, and other factors known to impact the outcome of elections, such as job reports numbers, and stock market performance.

Silver has been the subject of scrutiny for his methods and projections. Historically, public opinion polls have been used to assess where candidates stand in a particular race. Polls are used to provide a snapshot of public opinion at a specific time. They are not predictors of future outcomes, despite popular tendency to extrapolate from their results. Silver has broken away from this traditional approach by using predictive analytics in an attempt to forecast the probability of election outcomes. As such, he has been criticized. Criticisms include accusations by supporters of both parties that Silver's methods have been biased in manners that disadvantaged their candidate. However, despite any political leanings Silver may have, his track record of successfully modeling the election outcomes in the 2008, 2010, and 2012 elections is evident of his reliance on a nonpartisan, data-driven approach devoid of personal bias. Silver's work has given validity to the use of predictive analytics as a tool for forecasting the outcome of democratic elections in the United States.

Campaigns and Advocacy Groups

Predictive analytics are not only used to predict election outcomes. They have become a strategy for campaigns and advocacy groups to increase their efficiency by enhancing the accuracy of audience targeting, thereby optimizing the allocation of limited financial and human resources. Predictive analytics as a tool for driving civic or political action rely on sourcing massive amounts of data that citizens share about themselves through such means as shopping activities, subscriptions, Internet traffic activities, campaign

donations, and online social behaviors. Voter data are often purchased from data brokers such as Acxiom, or may be shared by businesses and organizations supporting a candidate. Powerful analytic software is used to structure the data into profile groupings of individuals with common characteristics. Models are constructed to predict which profiles will respond to particular messages.

Targeting is used to reach out to individuals who are not yet persuaded, but are likely to be persuaded by a message. This way, resources are not wasted on individuals who already support a cause or candidate. Resources are also not wasted on individuals who are not likely to be persuaded by a message because they already oppose the cause or candidate.

For example, *Frontline* (PBS) reported that in the 2012 presidential election, the Obama team used data mining and analytics in a coordinated effort to turn out the vote. The Obama campaign gathered unprecedented amounts of data about potential voters by piecing together an individual's information from a number of different sources into a voter profile. That voter profile could contain hundreds of data points about an individual. This coordinated data mining effort sourced data from voter records, consumer databases, donor lists, volunteer databases, data gathered during canvassing, smart phone applications, and social media such as Facebook profiles.

These voter profiles were then microtargeted based on their profile classification, derived from analysis of demographic data points such as gender, age, and marital status, feedback the individual may have given during canvassing, as well as consumer habits that were known predictors of political orientation such as entertainment preferences or type of car owned. Voters were targeted with messages highlighting issues important to them to increase the probability of activating their support.

Predictive analytics can also be effectively used by organizations with fewer resources than a presidential campaign. For example, the Sierra Club advocacy group has used predictive analytics to target potential supporters of the organization's environmental stances. As consumers share more information about themselves, and campaigns and advocacy groups build larger databases,

more detailed profiles can be produced, resulting in better message targeting and enhanced predictive ability.

Criticism

Despite its utility, predictive analytics are not free from criticism. Privacy advocates are concerned with the amount of data that is gathered about the public, and how that data is used. While campaigns have an increased ability to serve targeted campaign messages based on information voters voluntarily share, data gathering that occurs without their prior knowledge. This particularly concerns online data mining. Many Web sites track users' online behavior such as keywords they use in search engines, Web sites they visit, and items they put in a shopping cart by planting a cookie on visitors' browsers. This information is used to produce tailored campaign messages.

For example, a campaign in partnership with advertising networks, might serve an ad related to health care to users who frequent health Web sites. The main concern about this practice is that users are often not informed that their behavior is being tracked by sites, and thus are deprived of the opportunity to give informed consent for the use of their information. As campaigns gain more information about users, and users lose control over access to their information, this data mining practice could be used to manipulate voters, for example, by inordinately exposing them to a particular political viewpoint. To ensure user privacy and protect users from potential misuse of their information, it is essential to spell out user-friendly privacy policies such as opt-in policies asking for user affirmation prior to data gathering.

Conclusion

Altogether, it can be expected that the role of predictive analytics in the political arena will grow. While businesses, health care, and other arenas look to big data to understand and more effectively target audiences, so will campaigns and advocacy groups. Without changes to privacy laws and policies, access to large amounts of detailed consumer data will likely continue in the future. With continued advances in computing power for data storage and statistical modeling, organizations will be able to build increasingly

advanced predictive models and more precisely understand audiences and forecast outcomes.

Presidential Policy Directive 20

Presidential Policy Directive 20 was issued by President Barack Obama in October 2012 in an attempt to formulate a coherent strategy on cybersecurity with a particular focus on formulating a distinction between “offensive” and “defensive” policy responses. The full text of the directive is classified. Media and public information sources have provided information on some general provisions of the directive.

The directive represents a use of executive power in the field of national security and exhibits the broadening of conceptions of national security. Exploring the context and implementation of Presidential Policy Directive 20 provides an opportunity to learn more about national security policy and its potential impact on the media and civil liberties. As cybersecurity becomes a larger part of American national security policy, examining policy responses from a variety of angles becomes crucial.

Cybersecurity is an emerging threat to governments, private organizations, and individuals. Particularly, the United States–China relationship increasingly focuses on responding to cybersecurity threats. In October 2012, then Secretary of Defense Leon Panetta noted that the Department of Defense is able to conduct both pre-emptive and retaliatory cyberattacks. Panetta noted that cybersecurity was an area where the Department of Defense would respond. As of fall 2012, 13 units were formed by the U.S. military to respond to cyberattacks. In addition, President Obama has sought to build an alliance and coordinate cybersecurity with China, and has provided assistance to other nations throughout the world. A little understood, emerging policy area, much of the activity regarding cybersecurity has taken place through confidential directives that represent a broad exercise of executive power.

Presidential Policy Directive 20 was issued as a response to the threat of cybersecurity. While the full text has not been released, a fact sheet has been provided by the Obama administration. The fact sheet notes that as the directive is implemented, it will seek to follow the Constitution and existing law. The fact sheet, which offers very little substantive information, emphasizes the coordinating of activities across national and international boundaries. In addition, it is suggested that policy will be designed to respond to threats, rather than taking preemptive action. Differentiating between two distinct areas of cybersecurity, responding to threats on government networks as opposed to exploring potential threats on private networks is the key distinction made in the directive.

The *Washington Post* was one of the first major news outlets to report on presidential Directive 20 in a November 14, 2012, story. The *Washington Post* and other media outlets such as *The Hill* newspaper noted that the directive helped systematize and codify cybersecurity policy while also expanding the scope. The *Post* noted that differentiation between network defense and cyberoperations was established in the directive. Network defense primarily focuses on the government’s systems, while cyberoperations involves monitoring potential threats. Cyberoperations specifically refers to what happens outside of the networks of the federal government. The implementation of cyberoperations is an area of contention. The extent of cybersecurity efforts on private networks raises questions regarding transparency and the impact of security initiatives on electronic media and dissent.

Presidential Policy Directive 20 was also created in part because of the failure of legislation authored by Senators Susan Collins and Joseph Lieberman to advance. Since Congress was unwilling or unable to enact legislation, the Obama administration made use of executive power. Use of executive power in the area of national security has been widespread, particularly since the events of September 11, 2001.

Precursors

Presidential Policy Directive 20 represents an excellent opportunity to observe how the Obama administration in many ways continues directions begun during the administration of George W. Bush. In January 2008, President Bush issued

Presidential Policy Directive 54. While, like Presidential Policy Directive 20, the text has not been released, but some information is available on the contents of the document. Presidential Policy Directive 54 included 12 initiatives, and established the Comprehensive National Cybersecurity Initiative (CNCI). President Obama expanded on Presidential Policy Directive 54 in Presidential Policy Directive 20, making the distinction between the two areas of cybersecurity clearer, and expanding the authority of the military to respond to cybersecurity threats. One potential method of responding to cybersecurity threats beyond government networks is Einstein 3.

Einstein 3

One of the key facets focused on in the current CNCI is Einstein 3, a successor to earlier attempts to monitor government networks. Einstein 3 moves beyond monitoring activity on American government networks to explore federal government activity on private Web sites. Media accounts suggested that AT&T was the likely test case. Einstein 3 is in many ways an example of seeking to preempt threats before they achieve their goals of conducting cyberattacks. Some scholars have criticized the Einstein 3 program for poor design that makes implementation difficult.

Einstein 3 represents one of the first major initiatives taken beyond monitoring government networks. How and if cybersecurity extends into private networks is likely to provoke controversy in coming years. As scrutiny over government observation of personal data has become more known to the public, the difficulties of formulating policy that intrudes on the privacy of private businesses and citizens have become a large concern. One of the key challenges of cybersecurity is creating methods that identify threats while protecting privacy. Whether that goal can be achieved remains to be seen.

National Security and Cybersecurity

Presidential Policy Directive 20 represents a broadening of traditional conceptions of national security, beyond a traditional focus on military intervention, national security concerns, economic and trade issues, environmental issues, energy issues, and border security. Barack Obama's National Security Strategy is broad ranging, and

he has invited a wide range of policymakers to National Security Council meetings to discuss emerging national security issues. Presidential Policy Directive 20 is a continuation of what the Obama administration identified as a broad definition of national security.

Presidential Policy Directive 20 uses executive power to coordinate a policy response to cyberattacks. It broadens the concept of national security to include new threats from both state and nonstate actors. Criticism of the directive shows the dangers in balancing national security and civil liberties. Social media and new forms of technology continue to be a forum for political discourse, and policymaking is made without full transparency due to national security concerns. The creation of tools such as Einstein 3 provide the capability for monitoring networks that has the potential to raise questions. With controversy emerging from practices sanctioned under the USA PATRIOT Act, questions will continue to arise on whether vigorous cybersecurity practices could have a chilling impact on dissent and debate in the United States. In the years since September 11, 2001, the U.S. government has sought to respond to technologically sophisticated threats while balancing national security with transparent governance and opportunities for freedom of expression. As a result, conflict and criticism have arisen against both the Bush and Obama administrations, and from political figures throughout the ideological spectrum.

Press Freedom and Online/Social Media Security

Press freedom, but also freedom of press or freedom of media, is related to the concept of freedom of expression. It refers to journalists' right to communicate and express their opinions, without obstruction or coercive control. Press freedom is recognized as a fundamental human right, like the rights to freedom of opinion and expression by the United Nations (UN) Universal Declaration of Human Rights that states that everyone has the right "to hold opinions without interference, and impart information and ideas through any media regardless of frontiers."

Today, press freedom encompasses freedom not only of print media, but also of digital and other public media. The concept has a long history, dating back to the 17th century, with the emergence of free markets and economic liberalization. A press that is free from direct control was considered an important element for free trade. The evolution and development of press freedom is, however, not homogenous around the world. While the First Amendment of the U.S. Constitution and many Western countries defends freedom of speech, the modern free press only emerged in the 19th century in Europe, North America, and those countries experiencing liberalism and democratic reforms.

Despite important developments in legislation, today's journalists around the world are still facing discrimination, intimidation, and legal action, and sometimes must risk their lives to express their opinions on events. Reporters Without Borders, a nonprofit, nongovernmental organization that studies the freedom of journalists every year, has developed a World Press Freedom Index to compare the status of journalism around the globe. The organization's findings depict a highly problematic situation for press freedom, showing

that only 66 countries of 197 investigated can be considered free countries.

Social Media

With the advent of digital media, the concept of press freedom is extended to include the freedom of expression in shared online content. Due to the shrinking of the print media market and increasing public demand for online content, many media organizations have introduced online versions of their newspapers, and many journalists have blogs and social media pages in which they post their reflections, analyze events, and hold discussions with their followers.

Digital and social media allow for fast and prompt communication to large and differentiated groups of audiences. They create high visibility for news content. However, they also yield several risks. Online journalists may be accused of defamation, subversive behaviors, and even terrorism, and legal action over posting certain content online can occur. Unverified reporting and leaking confidential information are issues that have come to the forefront in the online environment. Since anyone can post anything in digital media, unless explicitly declared, individuals may be persecuted for content posted on their online pages, even if they were not the authors.

Online journalists are also less protected when posting content in social media. They are under more constraints because the content they post can reach audiences from countries with very different media regulations. In some countries, certain content may infringe on national laws. This means that journalists working online, such as news bloggers, are more exposed to legal issues than journalists working for traditional media that operates in a specific country or region with set rules.

Current regulations in most countries are short on guidelines or legislation for handling content in digital media, and often refer to regulations created for traditional mass media that are not suitable for the online environment. Under international treaties, online journalists who have posted sensitive content online can be extradited from their country to face trial and eventually be punished for serious publishing offences. One example is the case of Julian Assange, an Australian online journalist and activist, considered the

founder of WikiLeaks, who published sensitive U.S. diplomatic and military documents in 2010. Assange was accused of violating international standards of fairness, and may face the court if he returns to Australia.

The case of WikiLeaks has also raised debate on the impact of disclosing and sharing information online and on freedom of expression in social media in general. The rise of citizen journalism and the development of newer and more integrated social media platforms may have two main effects for society: they may advance transparency if online reporting is practiced ethically and in a moral manner, but they may also push governments and authorities to make stricter regulations and thus increase different forms of censorship in the name of security. In authoritarian countries, government controls on online content may consist of information blackouts in the state media, sophisticated Internet and text-message filtering as in China, and even personal intimidation and coercion of journalists as in Nigeria.

Yet, supporters of the positive effect of social media for press freedom argue that citizen journalism and news discussions and sharing in social media have become important elements for keeping political and economic powers under scrutiny. One example is the case of the Arab Spring. In several countries in the north African region, freedom of expression, especially press freedom, is limited. In these areas, social media has played a key role in challenging political authorities, to the extent that international news coverage of the revolutions was mostly possible thanks to bloggers, along with Twitter and Facebook activists.

Online Security

An important element linked to press freedom and social media is security. Specifically, online security concerns the safety of a computer and/or online environment, and deals with rules and measures to protect against threats such as viruses, spam, and hackers, as well as to enforce firewall and parental controls. The concept of security has become increasingly important in the development of Internet and digital technologies because of their increasing use and sometimes misuse. Under the auspices of greater press

freedom, many different types of content can be posted, shared, collected, and stored in the online environment. Yet, the availability of unrestricted content can undermine personal rights and national security.

Digital technologies have increased the possibility to create, post, and share content in the online environment; however, most Web 2.0 environments, including social media, require the creation of an account or profile to do so. When creating an online account, an individual releases some personal information. For some Web sites, the provision of a nickname and a valid e-mail account is sufficient but for others, more detailed information, such as gender, age, profession, and even the country of residence is requested. One of the problems of disclosing personal information online is that this information may be shared to third parties who are collecting information for specific purposes, for instance market research, but also in the name of state security. This creates a problem for online privacy, that is, the keeping of a person's information secret from others. In practice, monitoring social media can turn the online environment into a practice of public surveillance, of state control as the novelist George Orwell discussed back in 1949 in his novel *1984*. Indeed, special investigative units of states are constantly monitoring social media to find information on possible criminals and terrorists, raising public concerns on the extent of the state's intrusion into personal matters.

Online security problems can also occur when personal information is used by hackers for criminal purposes. Hackers may obtain personal data by, for example, deceiving people into providing their user names, passwords, and account numbers via deceptive e-mails, fake (spoofed) Web sites, or both—this is known as phishing. They may also do so by inserting malicious software, often referred to as “malware” or “spyware,” into a user's system. Other times, private information is simply made available unconsciously to the public because of the configuration of the online social media provider. A case occurred in 2012 when Facebook was accused of leaking access to information pertaining to profiles, photographs, and chat material to advertisers through Facebook users' accounts.

Third-party organizations also had the possibility to post messages and extract personal information from Facebook accounts. In these situations, online privacy is undermined and the risks of misuse of personal information have grown. There are situations of limited or no press freedom, typically in authoritarian countries in which securing anonymity of the source of the content and online privacy are necessary in order to maintain a certain level of free discussion. When human rights, especially freedom of expression, are limited, the identification of online journalists, bloggers, and activists achieved through bypassing online security mechanisms can have serious consequences for the lives of these people, and may seriously impact freedom of expression in those countries.

Debate

Promoting freedom of opinion and expression on the Internet in the name of transparency and accountability for powerful entities has raised other questions concerning national security and what impact a free flow of information can have in terms of prevention of crime, international terrorism, competition, and more. Skeptics of the free flow of information on the Internet call for more content regulation. Greater online security, both for individuals and countries, is desirable under certain conditions, but it requires the development of Internet-specific laws and harmonization of Internet governance, two areas of concern that are particularly difficult to tackle due to difficulties in reaching shared international agreements.

The lack of harmonization means that online content is regulated as well as sanctioned differently in different regions of the world, with greater consequences for personal security and journalists' freedom. It also triggers exceptions to the right of access to information. In the name of national security, states in nondemocratic regimes seek to suppress the free flow of information, for instance by Internet service provider control, whereas states in democratic regimes encourage self-regulation by private parties in order to regulate potentially harmful content. These actions do not find justification for the sake of security because they simply restrict personal access to otherwise available information, and do not prevent the disclosure of information considered confidential because of national security.

Conclusion

Overall, the debate on the role of the Internet and social media for the free flow of information and promotion of press freedom is still open and it is hard to foresee a clear direction due to diverse political and economic interests around the world. Yet, clear guidelines are needed at least to tackle ethical concerns about the privacy of information when collecting and managing information on people in social media, including the dissemination of such information to third-party organizations.

Pretty Good Privacy

Pretty Good Privacy, commonly known as PGP, is a user-friendly computer application used to encrypt e-mail correspondence. PGP can also be used to include an encrypted digital signature to an e-mail message without encrypting the message. PGP is the most widely used encryption software for e-mail correspondence worldwide.

Pretty Good Privacy was the creation of Phillip Zimmerman who, in 1984, first conceived of the idea of a widely available, cost-free, open source computer program that ordinary people could use to send and receive e-mail correspondence that could not be read by others. According to Zimmerman, his concept for PGP relied on a programming "breakthrough" that had occurred more than a decade before, involving the most essential (and most vulnerable) element in any secret communication scheme: turning plain text into coded text, and vice versa. Thus, if a user wished to send someone else an encrypted message, he or she had to give the recipient the necessary key to unlock the encryption code. The challenge was to develop a protocol to send the encryption key so that it could not be intercepted and thus make secret communications not so secret.

Zimmerman pondered the question of how to exchange encryption keys over a period of years, developing PGP's complex algorithms in the limited free time he had available between parenting and engaging in freelance work. It was not until a clause introduced by U.S. Congress in a proposed antiterrorism bill that Zimmerman threw himself into the task of completing PGP and making it available to anyone who wished to use it. Zimmerman first uploaded the source code to PGP into

a USENET newsgroup in June 1991, and invited people to use it for free. Shortly thereafter, PGP was used by human rights activists in what, at the time, was the intensely conflict-ridden region of the Yugoslav successor states, most notably in Kosovo, Sarajevo, and Croatia. It was also used in the early 1990s in volatile states including, but certainly not limited to, Guatemala. There, in 1992, Dr. Patrick Ball collaborated with the International Center for Human Rights Research in Guatemala (CIIDH) to develop a database of more than 43,000 human rights violations that he protected from the authorities through PGP encryption.

The Impact of PGP

At the time of the release of PGP, Zimmerman argued the encryption software "dramatically changed the security landscape." Zimmerman noted, "Before PGP, there was no way for two ordinary people to communicate over long distances without the risk of interception. Not by phone, not by FedEx, not by fax." Users, ranging from human rights defenders to students, wrote to Zimmerman to report that the only thing standing between them and oppressive regimes was his technology.

Zimmermann was promptly "considered the godfather of encryption software," according to the *New York Times*. Such wide attention had a downside for Zimmerman; shortly after its release, PGP came to the attention of the U.S. National Security Administration (NSA), the government body that oversees all issues pertaining to encryption. The NSA informed Zimmerman in February 1993 that he was being investigated for violating U.S. export control laws. Because the U.S. government considered encryption software weaponry at the time, PGP was restricted for export under a munitions clause of import/export. Interestingly, while at the time, it was illegal to transport PGP on a (then commonly used) floppy disk or computer hard drive, it was possible to carry a printout of the million or so lines of Zimmerman's computer code that instructed the functionality of PGP.

The NSA eventually dropped the charges in January 1996, after which Zimmerman founded the commercial startup PGP Inc., which was purchased by Network Associates in 1997. Zimmerman's prediction in 2000, that "We'll be accessing

the Internet all the time, which means a dramatic increase in security requirements,” eventually led him to a partnership with former U.S. Navy SEALs security expert Mike Janke and their start-up, Silent Circle, a security firm that encrypts phone calls, texts, and video calls. Silent Circle reported a 400 percent increase in new customers after the 2013 disclosures about the National Security Agency’s surveillance efforts.

Price, Tom

Tom Price is a Georgia Republican whose reputation for uncompromising conservatism, electoral performance, and legislative leadership in both the Georgia State Senate and U.S. House have given him the prominence to be a contender for the position of speaker of the House or the U.S. Senate. As a member of the U.S. House, he has been adept at using social media to promote his public policy positions and political ambitions.

Encompassing many of the relatively affluent, predominantly white, suburban municipalities in north metro Atlanta, including Alpharetta, Brookhaven, Doraville, Dunwoody, Johns Creek, Roswell, Sandy Springs, and Tucker, Price’s 6th Congressional District was previously represented by current Republican U.S. Senator Johnny Isakson. Before that, the seat was held by former Republican Speaker of the House Newt Gingrich. North metro Atlanta was the scene of very rapid suburbanization in the 1990s and 2000s, with small mill towns and farm towns transformed into outer suburbs inhabited by commuters.

That the long commutes to work and residential racial isolation common in the outer suburbs that comprise most of the 6th District could brew up a toxic mix of frustration, social alienation, and political extremism is plausible. Certainly a reputation for denouncing political opponents and for refusing to compromise on the basis of principle would find such an angry audience receptive. Although the district is more racially and ethnically diverse after Georgia’s congressional electoral map was redrawn to make way for a new 14th U.S. House district, it continues to be a safe seat for both the GOP and the incumbent. The fact that Barack Obama received a mere 35 percent of the vote in the 6th District in 2008 general election reveals its ideological complexion.

Price is a good fit for the demography of his district. A white, northern transplant like many of his constituents, he was born on October 8, 1954, in Lansing, Michigan, and earned both his undergraduate and medical degrees at the University of Michigan. Among the 50 wealthiest members of Congress, Price was reportedly worth \$8.5 million in 2009. He is married to Elizabeth “Betty”

Clark Price, an anesthesiologist who is active in local politics in Roswell where the couple reside. Betty Price received her undergraduate education at Pomona College and her medical training at McGill University.

Political Career

Ambition is evident in a political career launched by winning a seat in the Georgia State Senate in 1998, where Price would serve first as minority whip, and then as majority leader, until his successful 2004 run for a seat in the U.S. House. The 6th District was an open seat that year because of Johnny Isakson's decision to run for a seat in the U.S. Senate. Price won unopposed. In 2006, he defeated his Democratic challenger, Steve Sinton, by a margin of 44.8 percent. In 2008, he defeated his Democratic challenger, Bill Jones, by a margin of 37 percent. Running unopposed again in 2010 and in 2012, he defeated his Democratic challenger, Jeff Kazanow, by a margin of 29.02 percent. If the margins of victory have decreased over time, they do not suggest vulnerability.

As he had in the Georgia State Senate, Price climbed into the GOP leadership in the U.S. House, becoming chair of the Republican Study Committee, or the fourth-highest-ranking party leader. However, in tracking toward the center after the electoral defeats of 2012, Speaker John Boehner informally but effectively backed the more moderate Representative Cathy McMorris Rodgers from Washington for that position and Price lost the leadership position. Together with the selection of a cohort of new, more moderate committee chairs, Boehner's support for McMorris was perceived by many conservatives as a purge by Boehner to move the legislative party, and with it the national party, closer to the ideological center.

High visibility led to Price being mentioned as a possible contender for speaker of the House, and more probably, a possible challenger to Republican Senator Saxby Chambliss in 2014. Populist conservatives like those who were active in the Tea Party Movement were unhappy with Chambliss for expressing willingness to compromise on restoring tax rates in budget negotiations after the 2012 general election. Refusal to compromise on taxes made Price popular among that same group. That, together with a campaign war chest

larger than that of Chambliss, would make him a formidable opponent.

Price's legislative voting record appeals to both economic libertarians and social conservatives. In 2011, the American Conservative Union awarded him a lifetime score of 97.14, indicating that he is one of the most conservative and perhaps the most conservative member of the U.S. House of Representatives. With respect to economic regulation, he has voted to reduce capital gains taxes, implement the Central American Free Trade Agreement, schedule the permitting of new refineries, and open the Outer Continental Shelf to oil and gas drilling.

Enthusiasm for the corporations engaged in offshore drilling earned Price a measure of controversy in June 2010. During testimony by BP CEO Tony Hayward, Republican Representative Joe Barton of Texas echoed comments previously made by Price as chair of the House Republican

Tom Price, a member of the U.S. House of Representatives from Georgia's 6th district, speaking at the Freedomworks New Fair Deal Rally outside the U.S. Capitol, Washington, D.C., on April 15, 2013. Price is known as an uncompromising conservative.

Study Committee that, by agreeing to create a \$20 billion escrow account to pay for damage caused by the 2010 oil spill in the Gulf of Mexico, BP had been subjected to a “shakedown” by the Obama White House. The term connotes organized crime. Unlike Barton, Price did not apologize for using the inflammatory term.

Price has voted against modification of bankruptcy rules to avoid foreclosures, regulating the subprime mortgage industry, economic recovery/stimulus spending, increasing the debt limit, permitting corporate shareholders to vote on executive compensation, granting tax incentives for renewable energy, and regulating tobacco as a drug.

With respect to social policy, he has voted to award equal protection under the Fourteenth Amendment to human fetuses, ban federal government health coverage for abortions, restrict interstate transport of minors for abortions, ban human embryonic stem cell research, prohibit federal funding for Planned Parenthood, and restrict the definition of marriage as the union of one man and one woman in the U.S. Constitution. He voted against prohibiting employment discrimination based on sexual orientation and recognizing hate crimes targeting sexual minorities.

The Roswell Republican also predictably voted on a range of other issues that are important to conservative constituencies: against gun control, in favor of roving wiretaps in terrorism cases; against congressional oversight of CIA interrogations, in favor of ending federal funding for National Public Radio, for marijuana prohibition, and for making English the official language of the United States. Finally, his votes have been consistently conservative on two issues about which he appears especially passionate: health care policy, and U.S. foreign policy toward Israel and Palestine.

These same issues feature prominently in messages conveyed in a manner originating in the era of print media, such as newspaper op-ed columns and press releases. However, they may gain wider circulation because they are reproduced online on Web sites controlled by the House GOP. Thus, a September 19, 2012, op-ed column posted on the Republican Study Committee Web site, “Rep. Price Op-ed: Where Leading From Behind Leads,” expressed strong disapproval of President Obama’s response to events in the Middle East.

He ended the piece with a denunciation of the president for attending a fundraiser in Las Vegas on the evening following the attack on the U.S. consulate in Benghazi.

Social Media Use

Social media represents something different in the relationship between elected officials and their constituents because it permits interaction that is relatively inexpensive in both time and social risk for the constituent. While the delivery of speeches before groups and/or the issuing of op-ed columns and press releases also permit responses from constituents, these require more from the constituent because they must rise to ask questions during a town hall meeting or write a letter to the editor after reading an op-ed column.

The greater ease of responding to social media such as YouTube videos and tweets invites increased interaction. Online conversation may reinforce the abstract connection that develops when constituents recognize the elected official and approve of his or her public policy position and legislative voting when it is the subject of news coverage. However, it may also establish virtual personal relationships that are as much akin to that formed via case work as it is through recognition and approval of position taking and legislative voting. From the perspective of the elected official, a virtual personal relationship may be less costly than undertaking the problem solving required of legislative casework.

Although it obviates the possibility of developing a virtual personal relationship, the possibility that constituents or anyone else online may anonymously respond to social media content dramatically reduces the attendant social risk. As a consequence, conversation is all too frequently uncivil. That is evident in the commonplace discourtesy and practiced unpleasantness by participants on some message boards and chat rooms. Dogmatism, hyperbole, and vituperation are predictable features of unmonitored discussions of political topics. The reason for this is that some individuals succumb to the temptations of anonymity by presenting an alternative identity that psychiatrist Elias Aboujaoude has termed the “disinhibited e-personality.” Grandiosity, narcissism, impulsivity, immaturity, and the illusion of knowledge are its symptoms.

Lack of inhibition characterizes comments posted in response to a July 16, 2009, YouTube video of a committee hearing in which Price states twice that the health care legislation proposed by Obama administration will “destroy health care in America.” In addition to obscene language, one of the comments endorsed criminal punishment for political opponents:

Obama/Emanuel/Pelosi/Reid—just for their criminal medical service takeover—should be in prison at least.

Elected officials willing to mobilize supporters with strong ideological views walk a fine line between rallying them at public gatherings and on election day on the one hand, and being associated with their most extreme sentiments and actions on the other. To date, he has walked that line flawlessly.

Price is a vigorous tweeter. Jennifer Golbeck, Justin Grimes, and Anthony Rogers identified 12 categories of tweets by congressmen in their content analysis of congressional posts, including two that characterize much of Price’s tweeting: opinion and announcement/advertisement. Moreover, many of his opinions are about a small set of issues: health care, government spending, and support for Israel. Thus, in the weeks after the November 6, 2012, election, he offered multiple opinions critical of the health care and budget policies of the Obama administration and supportive of Israel. On December 4, he posted this message:

We do not need a government #healthcare takeover & President Obama’s higher taxes. We need patient-centered reforms.

On November 29, in an apparent response to the majority decision of the United Nations (UN) general assembly to grant the Palestinian Authority the status of a nonvoting state, he posted this message:

Path to Palestinian statehood is between Ramallah and Jerusalem—UN [United Nations] scoring political points only makes things worse.

He also frequently announces or advertises his appearances on television talk shows and

newspaper op-ed columns. On November 29, he also posted these messages:

As I explained today on @TeamCavuto, I do not favor raising the tax rates. Watch to find out why—[#fiscalcliff](http://bit.ly?YvaEzt) #tcot

Check out my op-ed: Falling for Hamas’s media manipulation <http://www.washingtonpost.com/opinions/falling-for-hamass-media-manipulation/2012/11/28/4d7b9498-39a1-11e2-8a97-363b0f9a0ab3story.html...#gaza#palestinians>

To generate and manage social media, Price hired a director of new media for both his personal and leadership offices, in addition to his regular press aide. He has also created multiple Web sites to post press releases and op-ed columns. Much of the content is innocuous. Examples include press releases informing readers that the Congressman had been named a “Defender of Liberty” by the American Conservative Union and a “Defender of Economic Liberty” by the Club for Growth. However, there are also messages like the denunciation of a reported “stealth survey” of physician’s offices by the Obama administration that ends with the apocalyptic warning that “Big Brother is destroying health care in America.”

Primacy Effect

An important aspect of social media is their immediacy. Social media have been built on speed and instant communication. This is a shift in some ways from the previous view, like the moral in the fable of the tortoise and the hare, that slow and steady wins the race. The concept of primacy has invaded the world, and education is being forced to rethink content and pedagogy. The concept of primacy has a history in psychology, neuroscience, and education. In the early 1900s, psychologist Hermann Ebbinghaus studied the effect of serial position on recall, and demonstrated that individuals are more likely to retain information presented at the beginning and end of a group or session. Later, Frederick Lund applied the concept to persuasion; others studied the impact of position on significance, or cognitive bias.

Rather than previous methods of communication, such as newspapers or television reporting, social media sites such as Twitter and Instagram have become popular based on the perceived value ascribed to instantaneous communication across boundaries. Two main aspects of social media that are examined in conjunction with primacy are the degree to which the idea or information spreads widely, and how it is memorable.

Spread of Information

Malcolm Gladwell, Henry Jenkins, and others have investigated why some units of information spread, and others do not. They have discussed

how the spread of ideas is formed by a blend of the thing itself, and the process. In some ways, it is similar to what happens when a good product is joined with a brilliant advertising campaign: this is the essence of marketing. Jonah Berger has described six principles that contribute to the "contagiousness" of something. The first is social currency, or how the message is crafted to achieve the desired result. In social media, it is important to know something that will make others—especially those who count—think that one is smart and on the cutting edge. Individuals may become known as the person to go to for the latest information on a particular set of knowledge, giving them insider status.

Second, ideas spread when they are triggers, something that comes to mind when a related idea surfaces. This is a common phenomenon when people surf the Web and go from topic to topic as their minds form associations. Third, when strong emotion accompanies something, it is more likely to spread; this explains the plethora of videos of adorable cats and toddlers that find their way to everyone's e-mail or Facebook. Fourth, making something visible or public contributes to spread. Author M. Lindstrom discusses the concept of mirror neurons in the brain that seem to be responsible for the human tendency to imitate. Something that is public is seen, and more likely to be copied. Fifth, individuals are eager to pass on things that are useful and have practical value. If something may help another person, it will generally spread. Finally, presenting information via stories rather than explanations will lead to dispersal. Messages embedded in a narrative will not only spread, but be remembered. Within these stories, certain themes will resonate more than others. These themes often combine a number of the six factors, such as emotion, triggers, and practical value.

Some researchers have begun to examine the nature of identity and community in light of spreadable media. Word-of-mouth is still just that; despite the proliferation of gadgets and applications, most human interaction is face-to-face, verbal, and personal. One study found that of Facebook friends, only 7 percent were people that users have never met in person, and only 3 percent are people they only met one time. The remaining connections may not be active, such

as friends-of-friends and social ties that may be seen as potential sources of trusted information, thus contributing to spreadability. Author Douglas Rushkoff describes content as something to be stored for the next conversational opportunity; still spread, but in human terms as well as through social media. Primacy without these other factors does not appear to be enough to result in dispersal, but it is a potent force when combined with other attributes.

Retention

Within the incredible amounts of content continually changing on the Internet, some is retained, while most is forgotten. Not all information that is spreadable due to primacy will “stick”; stickiness is defined as ideas that are understood and remembered, and often have a lasting impact or cause someone to change his or her opinion or behavior. Primacy may be enough to gain attention, but something else is needed to command retention. Educators often need to balance these two factors and utilize both for the most critical knowledge and skills.

Primacy alone is not enough to ensure that a message will be noticed or retained. However, social media have increased the seeming importance of staying informed up to the second as to the latest nugget of information that no one else knows. Social status is often achieved by being the one to pass along something new. Rushkoff has coined the term *presentism* to describe the diminishment of everything that is not happening right now. From status updates to location check-ins on Foursquare to tweets and trending topics, there is a lure to the instantaneous. In education, questions remain regarding the balance of freshness with value. It is not always clear what may get lost in the excitement, or how others may manipulate based on “buzz.”

Privacy

The increased transparency, expression, and content sharing created by the proliferation of social media has been paralleled by significant global concern about a corresponding reduction in individual privacy. Although online privacy issues have existed since the onset of the Internet, they rose to the forefront of public consciousness in early 2012 due to well-publicized media coverage

of privacy stories, including Facebook privacy changes, the Obama administration's call for a Consumer Privacy Bill of Rights, and increased Federal Trade Commission scrutiny and fines for privacy failures. The Internet vastly increased the amount of personal information accessible and visible to the public, as well as the aggregation and tracking of that data by governments, private companies, and political campaigns. The lack of privacy in social media and the Internet is both a platform upon which politicians have campaigned, and a source of public embarrassment when online incidents expose their personal lives.

The modern conception of privacy refers to individuals' ability to control the context and

extent to which their personal information is disclosed on the Internet. Privacy scholars like Professor Daniel Solove believe that today's definition of privacy, to which the notion of personal control is integral, has evolved from a narrower right to be let alone, and is culturally dependent. Solove posits that privacy's importance to society stems not from a desire to hide negative behavior, but rather because it fosters positive democratic traits like free speech and expression. The surveillance that causes a lack of privacy is often accompanied by censorship because individuals inhibit themselves when others are monitoring them.

The rise of social media was largely responsible for this definitional shift in privacy, as many individuals could share detailed personal information with greater ease in larger volumes. However, also saw drawbacks from failing to adjust their privacy settings, frequent privacy policy changes, increasingly common undisclosed tracking and the aggregation of data and metadata by commercial interests, and external use of their posted content in unexpected situations, including in hiring decisions and legal proceedings. Increasingly, private social media companies aid law enforcement investigations both proactively, such as Facebook scanning all uploaded photos to identify known images of child pornography and referring suspects to law enforcement, and reactively, by responding to subpoenas and administrative requests for the personal information of their members. The National Security Agency's large-scale surveillance of U.S. residents also includes social media sources.

Although social networks do not usually have authority to refuse such data requests, they can challenge the request's validity and notify the individual it concerns. The 2012 case of *Harris v. Twitter* was a notable example: after New York law enforcement officials sought three months' worth of tweets and other Twitter information about Malcolm Harris, a Twitter user who was involved in the Occupy Wall Street protests, Twitter fought the subpoena's grounds and argued on behalf of its users before having to turn over Harris's data.

WikiLeaks

Few privacy topics have been as contentious as WikiLeaks. Founded in 2006, the nonprofit

Julian Assange, standing center, speaking at the Occupy London protest on October 16, 2011. Assange founded WikiLeaks, a nonprofit organization that published millions of classified government and corporate documents under the constitutional protection of freedom of the press.

organization WikiLeaks crowdsourced whistleblowing and went on to publish millions of classified government and corporate documents. Julian Assange, WikiLeaks's founder, was both lauded and deplored for releasing previously private records on such subjects as the Guantanamo Bay prison camp, the tenets of Scientology, and the Iraq War. Controversy peaked in 2010 when WikiLeaks released material provided by U.S. Army Private Bradley Manning, including a video that showed U.S. helicopters firing on unarmed journalists.

Pseudonyms

Social media privacy also encompasses choices about personal identification, particularly pseudonymity as it relates to political speech online. The U.S. Supreme Court highlighted the value of anonymous and pseudonymous speech in *McIntyre v. Ohio Elections Commission* (1995), noting that “protections for anonymous speech are vital to democratic discourse.” Individuals have embraced pseudonyms since the early days of the Internet, using them to sign petitions on crowd movement Web sites like Change.org, whistleblow about employers, review services, and freely express themselves. Many equate Internet pseudonymity with the online disinhibition effect and “trolling,” where individuals behave aggressively and offensively behind a pseudonymous mask when they would not behave similarly in unmasked interactions. The Nymwars movement began in 2011 when Google launched Google+ with a real-name policy requiring members to have real or real-looking names to use the service, stating that the policy encouraged more genuine interactions. After widespread protest spearheaded by the Electronic Frontier Foundation, Google+ moved to support pseudonymous identities. Facebook maintains a real name policy, but Twitter does not.

Facebook

No social network has been as influential and controversial on privacy issues as Facebook. Facebook emerged and supplanted Myspace as the largest social network in 2008, a shift that many researchers attribute in part to Facebook's more robust privacy controls compared to Myspace's “public by default” settings. Starting out with

membership limited to select universities and expanding throughout the United States, Facebook inspired millions of users to disclose their personal information under the protection of privacy by default and user-controlled privacy settings. Since then, Facebook has gradually eroded its members' ability to keep their information private, moving to a philosophy that people prefer to share than to limit their disclosures.

Facebook continues this trend of making more personal information public on the site after its March 2012 IPO, despite negative reactions, including a Federal Trade Commission settlement over deceptive privacy practices resulting in a 20-year series of privacy audits, a multimillion-dollar lawsuit settlement for using members' images in Sponsored Stories advertising, and protestation from members. The Europe v. Facebook movement started by Austrian student Max Schrems encouraged Facebook members in the European Union (EU) to request their stored information from the social network, overwhelming Facebook's staff and resulting in hundreds of pages of Facebook records on each individual. In July 2012, Senator Al Franken questioned Facebook representatives and other experts in a Senate hearing on Facebook's use and storage of biometric data through its facial recognition system, suggesting that widespread use of such technology could have chilling effects on political speech, among other concerns. After an investigation by Ireland's Data Protection Commissioner, Facebook disabled facial recognition for EU users.

Negative Effects

Both private individuals and politicians have dealt with the negative effects of unintentional or unwanted disclosure of their social media content. One notable example is high school teacher Ashley Paine's firing after a Facebook photo surfaced of her holding a beer while on vacation. Data aggregation companies like Social Intelligence record social media posts for up to several years, even if the individual deleted them, and sells the content to hiring managers who make employment decisions based on it, despite individuals believing it to be private or deleted. Republican vice presidential candidate Sarah Palin's Yahoo! e-mail was hacked after

a member of the hacktivist group Anonymous guessed the answers to her security questions based on publicly available online information about her, and Democratic Senator Anthony Weiner resigned after the sexually explicit photos he tweeted to a young woman became public. Because the Internet makes public gaffes much more visible and accessible than ever before, the EU is considering creating a “right to be forgotten” through regulation that would force social networks to remove users’ submitted content if they later request to do so.

Advertising

The “pay with your personal information” business model of many social networks and other free Internet services that derive a majority of revenue from advertising has led to a rift between privacy advocates and advertisers. Online data collection and tracking of site visitors are significant factors powering monetization. Advertisers argue that the tracking data they collect is aggregated and not personally identifiable. Privacy advocates such as University of Stanford researcher Arvind Narayanan counter that tracking data is often identified or easily linked to individuals, thus posing privacy concerns. The debate often centers on tracking’s possible value to Internet users, with advertisers saying that users prefer personalized advertising, and privacy advocates arguing that most consumers are unaware of the tradeoff they make with their personal data by using ad-funded free services.

Research suggests that consumers are largely ignorant of the existence of online tracking, which is typically invisible to the user, but that consumers who learn about the practice dislike having their online behavior tracked and analyzed. The chief Internet standards organization, the W3C, began standardizing a Do Not Track browser header in 2009 that many of the major Web browsers have included in their settings. Microsoft created controversy in 2012 when it enabled the Do Not Track request by default in Internet Explorer; major advertising groups stated that they would ignore these requests. The Do Not Track header does not specify how a receiving Web site or advertiser should react to it, and current cooperation is voluntary and virtually nonexistent. U.S. lawmakers have stated that

they may enact regulation to make Do Not Track enforceable to limit personal data collection if the advertising industry’s self-regulatory efforts fall short of protecting user privacy.

Political Campaigns

The use of both social media and personal data has become integral to modern political campaigns, allowing candidates to engage with and target eligible voters with previously unforeseen precision. Big data was a focus of both parties in the 2012 presidential elections, with the Obama and Romney campaigns collecting voter information through their official social media pages, Web sites, and apps. The campaigns combined online data with offline records from data brokers, including voting history and past political contributions, to build profiles on eligible voters for advertising purposes. The campaigns then targeted eligible voters with advertising and sought to enlist those with higher influence in their social circles to endorse a candidate, aiming to change the minds of undecided voters.

Legislation

Preceding the election, in February 2012, President Obama called for a Consumer Privacy Bill of Rights that, if codified, would grant Americans greater control over and access to their personal data online. Personal privacy remains a bipartisan issue in the United States, although the impact of privacy technology on industry has led Republicans to largely disfavor government enforcement of privacy rights, while Democrats tend to favor it.

In 2012, social media rose to protest proposed laws with privacy-infringing implications. In January 2012, Internet users across the globe united through social media and Web site content blackouts to protest and ultimately defeat the Stop Online Piracy Act (SOPA), with Web sites like Wikipedia and Reddit leading the movement. SOPA followed a similar bill, the PROTECT IP Act (PIPA). The EU Parliament rejected a multinational treaty to combat intellectual property piracy, the Anti-Counterfeiting Trade Agreement (ACTA), in July 2012. These bills were criticized for allowing overbroad surveillance to justify a reduction in online piracy and copyright infringement, which critics argued would violate

Internet users' privacy and promote censorship. The future of online privacy is uncertain while tracking-heavy legislation like the Cyber Intelligence Sharing and Protection Act (CISPA) lingers in the U.S. legislature.

Pro-Choice and Pro-Life

Even before the existence of social media, the proponents of the pro-choice and pro-life perspectives on abortion have used print and television/film media to present their respective views. The opposed positions stem from the landmark U.S. Supreme Court case of *Roe v. Wade*, which removed abortion laws in all 50 states. This made abortion legal through all nine months of pregnancy. Forty years later, state legislators have worked to provide women and girls with legal protections. Aligned with legislation are the opinions of voters who tend to self-define as being pro-life, which prohibits abortions under almost

any circumstance; or pro-choice, supporting a woman's right to choose.

A variety of advocacy groups promote the agendas of these polarized groups. While the terms *pro-life* and *pro-choice* seem to represent a clear dichotomy, many individuals fall on a continuum. While they might not choose an abortion for themselves, they do not think that they should make decisions for others. Some are willing to make exceptions in the case of rape, health risks to the mother, or severe genetic abnormalities.

Before *Roe v. Wade*

Abortions have been performed, in every society, for thousands of years. Some historians suggest that abortions were legal in the United States from the time of its first settlers. Abortions were available, openly advertised, and performed at the time that the U.S. Constitution was adopted.

State laws making abortions illegal passed in the mid-to-late 1800s. Specific state laws were implemented for a variety of reasons. Doctors were the strongest force behind the criminalization of abortion. No longer would "alternative" practitioners like midwives, homeopaths, or apothecaries compete with them for patients and fees.

Abortions were extremely risky and were often carried out by well-respected doctors armed only with outdated medical educations and absent hospitals (which were uncommon) and antiseptics (as of yet unknown). While medical practices improved due to scientific discoveries and improved methodologies, most women in need of abortions had to resort to "back alley" illegal practitioners who could not utilize the safer procedures that were available.

In order to ensure that others would not perform abortions, the American Medical Association (AMA), newly established, declared that abortions were dangerous and immoral. All but one state had criminalized abortion by 1910, except when a doctor determined that a woman's life was at risk. Abortion became the doctor's domain. The Comstock (anti-obscenity) laws prohibited both legal abortion, as well as the distribution of information regarding birth control from the 1880s through 1973. The criminalization of abortions did not reduce the numbers, which were estimated to be as high as 1.2 million per year and included medical harm to thousands of women and many

deaths. Some doctors performed safe illegal abortions for the first half of the 20th century, until scrutiny forced many to stop.

Roe v. Wade

One-third of the U.S. states repealed abortion laws or reduced criminalization between 1967 and 1973. Yet, it was not until the 1973 Supreme Court decision in *Roe v. Wade* that remaining restrictive state laws were struck down. This decision allowed women to have legal and safe abortions performed by experienced medical professionals. The Supreme Court's decision supported the right to privacy of Americans regarding their bodies, including a woman's right to make personal choices regarding her pregnancy.

Reactions to the legalization of abortion resulted in a variety of responses. Supporters were confident that their battle had been won. Others found fault with the Court's decision. Opponents of legal abortions used a variety of approaches to undermine or limit the impact of the change in legal status. Some fought to prevent state and federal funding of abortions, whereas others disrupted clinics performing abortions, vandalized their properties, prevented access, and harassed anyone entering such establishments. Anti-abortion violence escalated over time. Clinics were bombed, individuals were physically attacked and some were murdered; these efforts created a hostile environment for women in need of services.

Over time, the Supreme Court has allowed some abortion restrictions. In 1992, in *Planned Parenthood v. Casey*, states were allowed to restrict pre-viability first trimester abortions, as long as women seeking services were not faced with an undue burden. There are restrictions in many states, ranging from requiring parental participation, mandatory waiting periods, and anti-abortion counseling. One disallowed requirement was that a woman involve her spouse in her decision.

Current U.S. Abortion Rights Challenges

Most recently, legislation has been proposed, opposed, implemented, overturned, and reinterpreted in a variety of states. These decisions include forbidding abortion, except in the case of maternal death, or requiring invasive ultrasounds. This topic has become increasingly volatile and politicized of late and has become part

of the sociopolitical movement identified as the "War on Women."

North Dakota is facing legal challenges following the passage of three abortion laws. These are the strictest in the United States and are expected to take effect on August 1, 2013. Arkansas has the most restrictive abortion ban, the Human Heartbeat Protection Act, which sets a 12-week pregnancy limit and detection of a fetal heartbeat, typically by an abdominal ultrasound. This legislation will also face court challenges. Intrusive trans-vaginal ultrasounds are required in Virginia following its recent abortion legislation. Mississippi requires doctors to have local hospital visiting privileges, which will result in the closing of the only remaining abortion clinic and restrict traveling doctors (who do not have hospital privileges).

Ten states have reduced abortion time limits to 20 weeks, based on the premise that a fetus can feel pain, which is disputed by most medical experts. Arizona and Georgia are facing legal challenges and a federal judge found the Idaho fetal pain law unconstitutional. The Pain-Capable Unborn Child Protection Act was debated in Congress and was passed by the Republican House but not by the Democratic Senate; President Obama stated that he would veto the legislation if it was ever passed. Originally, the legislation banned all abortions after 20 weeks; Democratic objections led to a revision permitting abortions in cases of rape and incest. However, this was still not found acceptable by Democrats who felt that this would require all rapes to be legally reported in order to qualify.

While some states are restricting and challenging a women's choice, others, such as New York, are reviewing legislation that would protect that right. Governor Andrew Cuomo introduced the Women's Equality Act in 2013, which would write the provisions of *Roe v. Wade* into state legislation to protect women's rights should *Roe v. Wade* ever be overturned. It was under debate in the New York State Legislature and it appeared that the Republican members were not allowing a vote on legislation.

Politics, Social Media, and Abortion Rights

Before the current use of social media and the Internet, both sides used the media to advance

More than 5,000 protested anti-abortion bills at the Texas State Capitol in Austin on July 1, 2013. The large turnout for the march was credited to Senator Wendy Davis's 13-hour filibuster and her efforts to block abortion-restrictive bills proposed by Governor Rick Perry. Live updates were tweeted throughout Davis's filibuster, as many celebrities tweeted "Stand with Wendy." The bill was temporarily derailed.

their views. The famous photos of fetus's feet were used in pro-life campaigns, and continue to appear on pro-life awareness pins. Wire hangers have been used as a symbol, and continue to appear on pins and posters as a reminder of the days of back alley and illegal abortions. The recent legislation and ongoing pro-life and pro-choice groups have made abortion policies and attempts to overturn *Roe v. Wade* political issues. In recent elections, most candidates have been asked to express their views on abortion legislation. Facebook, Twitter, Pinterest, and YouTube have been used to present abortion legislation perspectives.

In some cases these sources have instantly highlighted some of the controversial views of candidates. Todd Akin of Missouri said, "If it's a legitimate rape, the female body has ways to try to shut that whole thing down," while Indiana's Richard Mourdock expressed his view that pregnancy from rape was "something that God

intended." Both men lost their elections. Karl Rove, the Republican political strategist, wrote in the *Wall Street Journal* that these remarks allowed the media to focus on this social issue and were responsible for the Republican loss of two Senate seats. The "It's Not Just Akin" campaign (<http://itsnotjustakin.com>), funded by the American Bridge 21st Century PAC, highlights the abortion, rape, and women's health care views of other Republican politicians. It comes replete with Facebook and Twitter buttons to share with social networks.

Pro-Choice and Pro-Life Groups Using Social Media

Both pro-life and pro-choice organizations maintain Web sites and a presence on social media networks. A quick search on Facebook using the terms *pro-choice* or *pro-life* yielded multiple pages with numerous supporters on both sides.

The page with the greatest number of “likes” in the pro-life search was “I Am Pro-Life,” which has nearly 700,000 “likes.” While many other pro-life groups use Facebook, memberships are much lower.

NARAL Pro-Choice America has been described by *Fortune Magazine* as one of the top 10 advocacy groups in America. Its purpose is to politically engage to oppose abortion restrictions and to expand access to abortions. It has an official page on Facebook with almost 80,000 “likes.” Many of their state chapters also have pages. I Am Pro-Life also runs a media campaign from its Facebook page called “Here’s Why I’m Pro-Life,” where participants upload pictures.

Other organizations also use social media campaigns to advance their views. Students for Life (studentsforlife.org/) has a social networking presence on all the major social media networks. In 2013, it launched a campaign called lifeBLAST: A Pro-life Social Media Project to promote the pro-life perspective on social media. Choice Out Loud (choiceoutloud.org), a pro-choice advocate, presents *40*, an online film and interactive experience, which explores the personal choices made by young women in the 40 years since *Roe v. Wade*. It also appears on major social networking sites, and has buttons to allow viewers to share the video. These are just some examples of how groups use social media, and many more can be found.

Susan B. Komen Foundation and Planned Parenthood on Social Media

The strength of social media in the ongoing pro-choice and pro-life debate was demonstrated in the Facebook campaign against the Susan B. Komen Foundation when it announced that it was pulling its funding for breast cancer screenings from Planned Parenthood.

On January 31, 2012, the Associated Press ran a story on the defunding of Planned Parenthood by the Komen Foundation, which was picked up on Facebook and Twitter. While the Komen funds had only been used for breast screening services, Planned Parenthood’s role in providing birth control and abortion services clearly played a role in the decision. In many, Planned Parenthood is the only place that poor, uninsured, or underinsured women can receive these services.

Komen claimed that since Planned Parenthood was facing a congressional investigation by Rep. Cliff Stearns, its newly revised rules would not allow funding of such programs. Stearns, a Florida Republican, pro-life advocate, and chairman of the House Energy and Commerce Oversight and Investigations Subcommittee, initiated an investigation to learn if Planned Parenthood was illegally using government money for abortions. A 12-term incumbent, Stearns lost his primary election in 2012.

Cecile Richards, president of Planned Parenthood, credited Facebook and Twitter with drawing attention to the issue. The postings in support of Planned Parenthood far outnumbered those supporting the Komen decision. The social media campaign also resulted in increased funding for Planned Parenthood’s breast screening programs. The organization received more than \$400,000 from 6,000 donors. In addition, three large donors contributed: The Amy and Lee Fikes’ Foundation, run by the head of Bonanza Oil Company in Dallas, pledged \$250,000; New York Mayor Michael Bloomberg matched that \$250,000; and Credo, the mobile-phone company, promised \$200,000. Within four days, Komen’s board of directors reversed the decision, and announced that it would amend the policy to “make clear that disqualifying investigations must be criminal and conclusive in nature and not political.” Several top-level staff members resigned from Komen during the controversy. The foundation has suffered a decrease in donations, and had to cut back on some of its fundraising events.

Conclusion

The differences between those who favor a woman’s right to choose and those who wish to outlaw abortion will continue. State legislatures will continue to pass restrictive legislation that will eventually be reviewed by the Supreme Court. Voters will continue to elect both pro-choice and pro-life candidates, and both groups will continue to use social media to advance their causes.

Professional Bloggers

Blog activity took off during the late 1990s, almost on the eve of the 21st century. The term *blog* and its cognate word *Weblog* are generally credited as arising from an iterative coining process involving Web and Internet pioneers Peter Merholtz and John Barger in the late 1990s. A blog is an online, public, user-friendly publishing platform. Messages or "posts" are displayed in reverse chronological order, usually allowing comments. Hyperlinks are distinctive features of blogs ("It's the Link, Stupid" was the provocative title of a 2006 article about blogs published by the *Economist*), and they constitute the foundations of what is known as the "Blogosphere." The Blogosphere is not just the sum of all existing blogs, but is also a dense network of hyper-textual interrelations.

The expression *professional bloggers* can be considered paradoxical. Blogs are, by definition,

public disclosures of casual, subjective messages via the Internet, published by "amateurs" (in the sense that they are not necessarily professional public communicators), and backed by an accessible software that allows almost anyone to become a publisher. Blogs are much closer to longstanding Internet newsgroups than to the journalistic profession.

In any case, the combination of user-friendly software resources with subjective storytelling (even if it is performed by "experts" in any given field of knowledge) developed into networked structures of shared interests has given blogs their personality. Mainstream media at first sounded an apocalyptic note in their coverage of blogs ("The Attack of the Blogs" was the alarmist title of a *Forbes* cover story in 2005), but have since adopted blogging as a way of diversifying and "freeing" reporting by assigning journalists to run their own blogs under the umbrella of their legacy media.

Blogs brought these classical information outlets a more casual, compelling, and passionate style of reporting or commenting, the opportunity to deal with old or new issues in a new way, and a more personalized style of delivering information that could help bring journalists closer to their audiences and achieve a greater degree of engagement. Blogs boosted the development of hypertextuality in mainstream media, and fostered participatory and interactive practices (many of which did not go beyond the simulacra level), especially commenting. In recent years, the apocalyptic view, both in the case of blogs and Twitter, seems to have been overcome. Most journalists today praise blogs as "rewarding" software, and many have come to terms with Twitter and its 140-character format.

Professionalization

The professionalization of blogging is a complicated issue. A blogger can write about many of the same things that provide the subject of traditional journalistic attention, such as politics, science, religion, economics, and lightbulbs. Bloggers can even embark upon investigative activities about relevant public issues, and those who attract many readers can also become opinion leaders, can influence people, and can even earn some money. But the question of whether such

bloggers are fundamentally different from journalism professionals who use blogging as one of their many vehicles for distributing their work is still a live debate.

On one side of the argument lies blogging's genesis and significant history as a form of alternate and noninstitutional news and information, which professionalization would, by its very nature, impair or destroy. On the other hand, however, more legal apparatuses are being put into place to protect bloggers under the same shield laws and free speech protections enjoyed by information providers who work in commercial media organizations. Both the United Nations and the U.S. National Press Club, among others, have called for these protections to extend to bloggers who work to report political and social abuses in totalitarian states and emerging democracies alike, which would suggest that some versions of blogging have now morphed into a much more professionalized stature than previously experienced.

In a related debate, it is a substantive as well as a semantic challenge to distinguish between "real" bloggers, whom history insists are non-professionals, and those people who begin their professional journalistic career as bloggers and who never do anything else, even if they do that for legacy media like the *Washington Post* and the *New York Times*.

Finally, the fact that there are people who make their living writing as bloggers for specifically online outlets calls into question the role of quantity as an indicator of professional status. How many bloggers have to blog for a living before blogging, itself, can be seen as an activity in which both professional and impassioned amateur status is possible? It is a tricky question, but an important one, and an issue that illustrates a common journey experienced by many new media technologies, in which they begin their public life as "rogue media" offering alternatives to mainstream structures, but eventually, either become subsumed by them or spawn institutionalized versions of their earlier selves.

Both traditional journalists and bloggers have defined identities, and presumably they are fully satisfied with them. Purposely theoretical confusion and progressive conceptual assimilation of "professional bloggers" and "journalists" are

very likely to be driven, if one dives deeper, by forces that are not theoretical ones, even if they seem so. "Weblogs and Journalism: Do They Connect?" asked Rebeca Blood in a Nieman Foundation report published in 2003, in which the thorny issue of whether "Weblogs are a form of journalism" was raised. One possible answer, a decade later, is that perhaps they have been rhetorically pushed to connect too much.

Platforms traditionally associated with "professional bloggers" like ProBlogger, Mediabistro, or JournalismJobs, list job postings for "media professionals" and offer a mix of news and "virtual training" tips and tools. JournalismJobs is now part of AOL, and MediaBistro is owned by WebMediaBrands. Those are just some examples of the widespread institutionalization of the blogosphere. Out of the blogs with top ranking in the Technorati Top 100, most are owned by big media companies like AOL, Condé Nast, and CNN. One of the main arguments used by advocates of the "professionalization" of blogging is that, in fact, blogs do not often offer new information, but instead recreate, gloss, or directly plagiarize information from the mainstream media—that they are "echo chambers" of traditional media.

The blogger-as-amateur argument would maintain that bloggers, as individuals, have every right in the world to embark on this kind of activity, precisely because they are not journalists—they are bloggers. The blogger-as-professional side might respond with the observation that there are now so many different types of bloggers, all of whom blog for different reasons and under different conditions, that one can no longer legitimately use the word *blogger* in such a universalist and undifferentiated way. Of course, everything changes when recycling and remixing news media stories becomes part of the core business of institutionalized blog networks conceived as high-scale aggregators and much of the time owned by media conglomerates. It is sometimes the case that those same big media companies are the owners of some of the news media whose content is being remixed.

Conclusion

In the original sense of the word, bloggers communicate not as journalists but as people, citizens,

individuals, fathers, movie lovers, mothers, music fans, gourmets, as scientists, economists, politicians, pilots, teachers, origami enthusiasts, and participants in the entire range of human experience in a way that precludes or ignores the professionalization of any of those specific roles or activities.

That is the purist understanding of “blogger” as a type of performed identity, and may be their unique and ongoing contribution to the digital age. Blogging as an activity, however, has undeniably multiplied into many different things, some of which are antithetical to the original concept of the “Blogosphere” as a noninstitutionalized, unranked outburst of interventions performed in the global scenario of the Internet by impassioned and very often expert amateurs.

It may be that blogging, per se, continues its trajectory into the realm of career journalism; it may also be that the act of blogging calves into two—or several—contrasting functions in the larger Web-universe. It is too late to say that there is no such thing as a “professional blogger,” but the jury is still out on the degree to which this must be an all-or-nothing transition.

Project Vote Smart

Project Vote Smart is a nonprofit voter education organization. It aims to provide voters with independent, unbiased information about candidates and officials at all levels and in all branches of American government. Started by Richard Kimball in 1988, the organization compiles both original research and candidate-provided statements into a useful database of easily compared information. The organization delivers this data primarily through the Web site <http://www.votesmart.org>, although it also offers some traditional-format publications. The Vote Smart database includes candidates' and officials' voting records, biographical and employment background, ratings from a variety of interest groups, public statements, and campaign finance sources. In addition to directly transmitting information to voters, Vote Smart frequently provides data for journalism and political research.

To gather data, Project Vote Smart asks every candidate for national office and many candidates for state-level office to respond to its Political Courage Test, a list of questions that seeks to establish the candidate's position on 13 significant issue areas. Candidate response to the Political Courage Test has declined over the years that the test has been issued. The *New York Times* reported that when the organization first issued its test in 1996, 72 percent of candidates for national office answered the test. In 2008, only 41 percent of congressional candidates answered

the questions, and an organization spokeswoman confirmed that candidates are being told by their staff not to provide answers to Project Vote Smart because the information could be used by opposing candidates. As a result of declining response rates, the organization began determining candidates' likely positions on the Political Courage Test issue areas based on public statements made by the candidates. Project Vote Smart publishes these "inferred" positions, along with the statements researchers used to infer the candidates' positions.

Project Vote Smart demonstrates an issue-oriented approach to politics, which the organization identifies as a counterbalance to an overly partisan political process. While profiles for candidates and officials include partisan affiliations, the information system emphasizes candidates' stated positions on specific political issues. The Vote Smart database provides identical displays for all registered candidates, not distinguishing between major and minor party candidates. Similarly, the Vote Smart Web site folds the Democratic and Republican parties into its listing of 56 national political parties, a list ranging from the American Beer Drinker's Party to the Thermodynamic Law Party. The Web site explicitly targets partisanship as a problem. While many former political officeholders are on the Project Vote Smart board, the organization requires that no board member join "without being balanced by a political enemy." The organization also has a policy of not accepting money from any corporation or organization that lobbies, supports, or opposes candidates.

While Project Vote Smart provides voters with information directly through its Web site, it also provides this information indirectly by providing local news outlets with an important source of state and local candidate information. Dozens of local newspapers have used the organization's information in their profiles of candidates; many newspapers have also endorsed the organization's database to their readers as a good source of objective information. The Vote Smart database has also frequently been used by political scientists, who have found that it provides a uniquely consistent source of information about state and local political actors on biographical data, key votes, and issue positions. Studies that have

sought to determine the impact of additional public information on democratic participation have also made use of Project Vote Smart.

Project Vote Smart uses volunteers and interns to gather information on the over 40,000 political actors in its database. Most interns and volunteers work at the organization's headquarters in Philipsburg, Montana, although interns also work at the Project Vote Smart satellite office at the University of Texas at Austin. In addition to the information available on its Web site, the organization continues to develop new information products and outreach methods, including a national bus tour from 2007 to 2008 that was intended to help raise awareness of its database, and an interactive Web tool created in 2010 called VoteEasy.

Using the same data that is presented in static form in the database, the VoteEasy tool allows users to select electoral races and then select their preferences on political issues in order to identify candidates whose stated positions are closest to their own. The Project Vote Smart founding board includes a number of influential political actors, including former U.S. presidents Jimmy Carter and Gerald Ford, and current and former members of Congress.

Proxy Measurements

In the United States, televised political advertising is the main way that modern campaigns communicate with voters. Although viewers may learn facts while watching news programs, during which many political ads air, advertising appears during many types of shows, including those unlikely to convey political information. More to the point, such information has even less to do with the content of most political advertising; political knowledge, then, is a tenuous proxy for campaign and exposure. Proxy measurement is any attempt to measure something that cannot be measured exactly when one wants or needs to, and instead looking at what can be measured.

Using proxy measures in weight construction leads to a larger shift in survey estimates than when they are not included. An ideal proxy variable for a successful adjustment variable for a point estimate does not necessarily translate to the ideal variable when interest is in estimated regression coefficients or subgroup analyses.

Social Media Metrics

Appropriate social media aims should be measurable, and it is essential to understand the business process that a social media program will address or drive, because each business process drives specific metrics. For instance, metrics related to program objectives allow direct measurement of program success; fundamentally, the measure is about evaluating performance against objectives. To evaluate the robustness and effectiveness of every approach to social media measurement, one may ask three fundamental questions:

- Does the approach measure the right things in order to show the business impact of the programs and initiatives?
- Will stakeholders of the report receive the data and actionable insights required to make strategic decisions?
- Are the data and insights presented in a clear and concise manner that tells a story and makes it easy to understand and proceed?

Social media metrics are derived from three primary sources: program goals, with specific metrics directly tied to program or campaign objectives; business outcomes, with metrics designed to measure the business impact of the campaign, program, or objective; and channel-specific, with metrics that are unique to social channels, such as tweets and retweets. Ideally, a robust social media measurement program will have a well-rounded set of metrics from all three dimensions.

Metrics tied to program objectives allow for direct measurement of program success. Fundamentally, measurement is about assessing performance against goals. Business outcome metrics are used to connect social media programs and the business results they are designed to drive.

It is surprising how often social program objectives are biased toward channel-specific metrics (e.g., "likes" or followers), and not the specific outcomes desired for the program. Also, relying too seriously on channel metrics limits one to what one can measure rather than what one should measure. Understanding the social media objectives will suggest general parameters of a measuring program, and finally, the decision tool must operate within them. A good measurement strategy should be to take a holistic, integrated approach using methodologies, tools, and data from all dimensions, being able to track behavior of individuals, understanding how online behavior impacts offline behavior and vice versa. Metrics for all dimensions can be any of the following:

- *Exposure*: Opportunities to see, branded mentions, search rank, message inclusion, net positive impressions, change in responsiveness, number of followers, "likes"
- *Engagement*: Branded search, replicate visitors, duration, subscriptions and

acquaintances, URL visits, comments/post shares, communication evoke and maintenance, links, bookmarks/votes/likes

- *Influence*: Purchase consideration, changes in opinion or attitudes, association with the branding or attributes, notify a friend, likelihood to recommend to a friend or colleague (net follower index)
- *Action*: Visit the store, attend the event, buy the product, contact a politician, vote for/against, visit Web site, request more info

In the early days, efforts to measure digital and social media almost exclusively focused on Web analytics; today it is developing toward measuring the conversations and behavior patterns occurring within networking. The great rise in the popularity of social networks in the last few years presented new challenges in digital research and measurement: researchers were faced with measuring both the conversations and behavior patterns occurring within social networks, and understanding and connecting the underlying influences and motivations for the online behavior; finally, there are also the real-world, offline interactions and transactions.

- *Web sites*: Web analytics software provided an explosion of data and new metrics like: unique visitors, page views, click-through rates, duration, referring sites and conversions.
- *Social networks*: It becomes important to measure conversations and engagement: How often is the brand mentioned in conversation? What is the sentiment of the comments? How often is the brand recommended and by whom? Content and behavior analysis, including tracking technologies, are the primary measurement tools.
- *Offline*: Audience research, representing all the real-world offline transactions that may be of interest: Did someone visit the store or attend the event? Did they buy a product? Did they recommend the brand or product to a friend over coffee?

Scan and other digital sales data are important.

Conclusion

When trying to measure political participation, questions that might be asked include: Have you ever contacted any elected official? Attended a campaign event? Joined an organization in support of a particular cause? Contributed money to a candidate running for public office? How much do you enjoy keeping up with political news about campaigns and elections? How closely have you been following news about the race for the Democratic presidential nomination?

Psychographics

Demographics are the external, often visible characteristics of a person such as age, gender, nationality, or educational level. Grouping and describing individuals by way of the demographic categories into which they fit can facilitate analysis and description of groups and communities for public policy or organizational purposes.

Demographic analysis also provides a powerful marketing tool that enables audience segmentation and targeting.

Psychographics (or psychological demographics) provides an additional dimension for analysis, providing a framework for identifying and categorizing the internal characteristics of that person. While demographics can provide some insight into what will motivate a person's behavior, using psychographics to understand that person's values, attitudes, and beliefs can elicit a much more nuanced and reliable path to motivating that person.

These audience analysis methods have long been the standard tools by which marketing and advertising campaigns are constructed and deployed. As the complexity and power of mass marketing technology has become more sophisticated, so have the instruments by which the receivers of these campaigns are defined and targeted. The proliferation of interactive social media technology in the 21st century adds a great deal of depth and richness to the amount of psychographic information available, as well as offering more sensitive and immediate tools to measure message effectiveness. The constant reciprocal flow of information from policymakers through campaign managers and through millions of users back through policymakers and managers is especially potent in the pursuit of political outcomes.

The Evolution of Psychographic Research and Its Application

Trying to understand what motivates a person's buying decisions originally, though now applied much more broadly, became a core focus of marketing professionals and scholars shortly after the end of World War II. Understanding of the interrelationship of audience demographics, public opinion, and economic choices was a useful lens into consumer motivation and behavior. Then, beginning in the 1960s, marketers began to explore and map the consumer's "inner landscape" by way of a psychological profile.

In 1960, Arthur Koponen conducted well-designed quantitative studies designed to link consumer behavior with findings from standardized personality inventories. But results were found unreliable, "equivocal," and too abstract to be

useful. Ernest Dichter's qualitative investigations of subjects' motivations, while criticized as lacking sound ethical and scholarly foundation, produced better results. A blending of qualitative and quantitative approaches has been the norm since the mid-1960s. An early study of airplane travelers' patterns and preferences by Stanley Plog in 1967 produced one of the first psychographic models.

Since then, researchers have focused on fine-tuning their methodologies to produce higher construct reliability and validity, stronger predictive validity, and thus greater usefulness in achieving marketing goals. In developing increasingly dense and detailed psychographic profiles of potential consumers, it is possible to go well beyond the surface characteristics of demographic groups and to understand the attitudes, needs, and drives of complex individuals.

Using data from user-generated social networks such as Facebook, YouTube, and Twitter, researchers can develop multidimensional social profiles that provide highly accurate and useful behavioral, lifecycle, and lifestyle data. Researchers can track an individual's online behavior to gain insights into the mental and emotional realms where that behavior emerged. For example, as a user travels from Web site to Web site, a "click set stream" of "cookies" is produced. Data-aggregators might then map a mental model consisting of psychographic-derived motivations that could define certain logical connections among the sites. When the user updates his or her Facebook page, social profile data management tools such as GraphEffect, which does a linguistic analysis of status updates, can produce insights into his or her personality or measure purchase intent. Other forms of data-mining can link the user's purchase of baby furniture or other product key-indicators to his or her position in lifecycle and lifestyle dimensions.

Marketers' and social researchers' evolving ability to develop this level of understanding of individual consumers is closely linked to the ability to develop and deliver messages tailored to that specific consumer, in a specific realm of selection of action, at a specific time and place. Such disaggregation of huge markets into specialized clusters of consumers facilitates "variable data messaging," which has a much higher return on investment than mass-marketing techniques. Thus,

political campaigns are coming to rely upon voter segmentation strategies since the emergence of the communication systems produced by Web 2.0.

Political Communication

Insofar as political parties, their platforms, and their candidates can achieve their goals only by gaining consumer/voter “buy-in,” strategic applications of psychographic analysis and segmentation are crucial. The use of these psychographic profiles in segmenting and microtargeting political consumers is central to a 21st-century political communication model that harnesses the power of the networks and systems generated by social media.

The goal of 20th-century market research was to develop demographics-based approaches through which like-minded potential consumers could be aggregated into large groups of receivers for persuasive messages delivered through the mass media of radio, television, and print sources. In contrast, the major goals of 21st-century marketers are to develop tools for construction of accurate, detailed user profiles, to isolate and track trend data, and to trigger consumer engagement in issues using psychographic segmentation. In short, 21st-century market research is built on a foundation of segmentation, fragmentation, and microtargeting. Internet-based technologies and Internet-based user networks produced by the proliferation of social media facilitate progress toward these goals.

An integration of political science theory and practice with that of marketing specialists, which some have characterized as “e-democracy,” has evolved. This “new paradigm,” according to global marketing experts Patrick Butler and Phil Harris, requires that political parties refigure their focus from an essentially economic bottom line to one that recognizes the importance of “leadership based on citizen value and need” and the use-value of such “intangible resources” as interpersonal relationships, loyalties, and the power of social networks generated by bottom-up information flows.

Since Democrat Howard Dean’s pioneering use of Internet resources from 2004 forward, integration of psychographic data and social networks are increasingly vital in national campaigns. In the 2010 U.S. election cycle, a number of studies focused

on the online political campaign and candidates’ adoption of Web-based messaging resources. One such study by Jeff Gulati and Christine Williams found that major party candidates for the House of Representatives were likely to have a Facebook page, Twitter account, and YouTube channel, with Republicans more likely than Democrats to be on YouTube. In the 2012 election cycle, microtargeting of potential voters with variable political messages based on data mined from social networks and other Internet sources was highly effective. Some strategists suggest that the ability to identify and tap into demographic and psychographic dimensions of the electorate were deciding factors in the outcome of several key elections.

Public Affairs Council

The Public Affairs Council is one of the largest associations for public affairs professionals worldwide. It seeks to advance the field of public

affairs and promote ethical standards by educating public affairs professionals. Public affairs, which includes the practice of lobbying, refers to organizational activities concerning the socio-political environment, and specifically to the management function of helping an organization generate political power and influence public opinion.

Public affairs activities can involve lobbying; monitoring and predicting political, legal, economic and social developments; providing political intelligence and strategic advice; and assisting media relations specialists. Public affairs professionals work for consultancies, industry, trade bodies or associations, civil society, unions, regions, or municipalities. As more political activity moves into the online and social media sphere, the Public Affairs Council is playing an increasingly important role in self-monitoring activities for social media-based campaign and e-governance activities.

Structure

The Public Affairs Council is headquartered in Washington, D.C., and is made up of a volunteer board of directors and an executive committee, which runs the day-to-day functions. The board of directors comprises about 170 senior public affairs executives from leading corporations, associations, and consultancies. Board members are typically business leaders who commit to contributing to the different activities of the council, including speaking at conferences, serving as information resources, participating in council networks, and promoting membership. Board members are elected every two years. The Executive committee includes 16 board members elected for a term. The committee is in charge of overseeing networks, developing budgets, recommending new programs, setting staff performance goals, planning board meetings, and conducting other council business. Along with this, the Public Affairs Council has a foundation—the Foundation for Public Affairs—that conducts studies and produces benchmarking analyses on emerging public policy issues and trends that affect the practice of public affairs. The foundation is sustained by donations made by Public Affairs Council's members and supporters, mainly consisting of corporations.

Role of the Public Affairs Council

The role of the Public Affairs Council has extended over the years as a result of the increasing influence and relevance of the profession in the United States and in developed countries. The growth of public affairs in society is directly linked to political culture. Political systems that are generally supportive of business participation in the policymaking process promote the use and the diffusion of public affairs. Liberal and democratic political systems typically recognize the profession of public affairs, but regulations concerning the practice of public affairs vary across countries.

In the United States, professional recognition of public affairs has a long history. The practice of lobbying goes back at least as far as the late 18th century, beginning in the earliest days of Congress. Yet, professional recognition did not arise until President Dwight D. Eisenhower provided a national institutional framework to support the participation of the business sector in political processes. Eisenhower decided to establish the Public Affairs Council in 1954, originally called the Effective Citizens Organization.

For the first decade of its existence, the Effective Citizens Organization focused on training about half a million managers and executives on politics and government relations. Because of U.S. social unrest in the 1960s, community relations assumed greater importance among corporations to tackle social issues in the communities where companies operated. The Public Affairs Council created a dedicated post in 1968, the Urban Affairs Function, and engaged in annual training seminars on community relations by hiring specialists in urban affairs to serve member companies' needs.

During the 1970s, public distrust of big business and concerns about transparency in government increased, calling for stricter government regulation. Since then, the public affairs practice has been highly regulated, and the U.S. legislation requires extensive disclosure of which organizations use public affairs, how and where they use them, and what their budgets are. With the introduction of the Lobbying Disclosure Act (LDA) in 1995, public affairs professionals that are paid for lobbying at the federal level have to register with the secretary of the Senate and the clerk of the House.

Relevency Today

The Public Affairs Council works to support corporate members that face greater challenges because of the globalization phenomenon and the fact that U.S. corporations increasingly operate in international environments with diverse legislations, regulations, and cultures in practicing public affairs. Working at the global level also means that substantial differences in public acceptance of corporate involvement in sociopolitical matters exist. Because of the nature of public affairs activities, that is, influencing public opinion and politicians, public affairs is one of the professions that receives frequent criticism in terms of legitimacy, representativeness, transparency, accountability, and ethics.

While public affairs professionals can be highly influential in legislation formulation and decision making processes, they are not elected officials, thus they do not represent the interests of society. Consequently, they are not accountable to citizens or publics for the legislation formulation they promote. These concerns call for a greater role of the Public Affairs Council in training and preparing business leaders in handling societal pressures, and acting ethically and in a transparent manner.

Public Intellectual

Throughout history, academics and other highly educated citizens of democracies have contributed to public discussions about issues of broad concern. During the 20th century, the traditional media—books, newspapers, magazines, radio, and television—were the forums through which so-called public intellectuals contributed to their societies' dialogues, however, the specific outlets in which their ideas were published or broadcast tended to reach relatively narrow audiences. The explosion of social and other digital media in the 21st century offers the promise of the democratization of the reach and access of public intellectuals and their ideas. At the same time, scholars and social critics question the quality of certain online outlets, and therefore fear that the reputation of public intellectualism is in danger of being cheapened.

PIs and Politics

A public intellectual (PI) is a person deeply committed to the life of the mind and its impact on society. A PI draws on his or her intellectual resources and depth of knowledge in order to address a broad,

though educated public about serious national or transnational issues. While many PIs work as college professors, being on a college faculty is not a requirement for being a PI.

Indeed, many PIs work as journalists, media personalities, and/or as members of “think tanks”; for such people, the term *public intellectual* is not merely an informal social role, but is, in effect, their job description. The “day job” of academic PIs, by contrast, is typically that of professor: the majority of their time is spent teaching and publishing scholarly work, meaning their “public” general-audience-focused contributions, publications, and media appearances are a sideline, if often more lucrative than their university positions.

The origins of the term *public intellectual* are disputed, although it appears that the idea gained currency in late 19th-century France, when many of that country’s leading scholars and writers offered public criticisms of the government’s handling of the Dreyfus Affair, a political scandal involving accusations of treason and a military cover-up of evidence. In the United States, the idea that members of the academy should share their ideas with the public became popular in the 1930s, inspired largely by John Dewey, a university professor and educational reformer. Intellectuals’ contributions to public life—and public awareness of those contributions—became increasingly visible throughout the subsequent decades of the 20th century, fueled largely by the explosion of traditional mass media.

The relationship of PIs to politics is somewhat controversial. While most scholars see the role of PI as providing insight into, and solutions for, pressing political problems, others argue that PIs can be successful or respected only if they are nonpartisan and nonideological, or are at least open to opinions other than their own. In any case, most PIs’ public content—whether delivered in the form of magazine or newspaper articles, television appearances, blog posts, or Twitter feeds—is intended to shape public opinion. It tends to consist of political analysis and critique, calls for political and social change, and often offers specific recommendations for the execution of public policy, typically on issues such as war, education, the environment, the economy, and human rights.

PIs and (Social) Media

By definition, a “public” intellectual disseminates his or her ideas to the population at large; thus, to be a PI, one must find and cultivate a broad audience. Throughout the latter half of the 20th century, radio and television were the dominant media through which PIs disseminated their ideas, typically using outlets such as National Public Radio, C-SPAN, and public television. While even these outlets can be somewhat exclusive, PIs speaking about issues of political importance in such venues have had to find ways of translating often dense academic jargon into accessible, plain language. Magazines such as *The Nation*, *Harper’s*, the *New Yorker*, and *The New Republic*, and newspapers such as the *New York Times* and the *Washington Post* have also provided platforms for PIs to address pressing concerns at greater length, albeit to relatively narrow audiences. More recently, political/entertainment shows on cable television—chief among them *Real Time with Bill Maher*, *The Daily Show With Jon Stewart*, and *The Colbert Report*—have offered PIs opportunities to speak (usually while promoting a recently published book) on issues of importance to the nation. One scholar has even argued that Jon Stewart is the greatest public intellectual of this age.

The explosion of new forms of media—online-only publications, podcasts, and especially blogs and microblogs—have allowed PIs to greatly expand the dissemination of their ideas and work. Indeed, several scholars have argued that social media have made the early 21st century the best time in history for public intellectuals because the growth in digital publication has exponentially increased the quality, diversity, and accessibility of PIs and their ideas.

While some critics have expressed reservations about the darker sides of the blogosphere and its potential to tarnish the reputation of PIs who use them, others have cheered social media’s interactivity and ability to break down the barriers to PIs that are often erected by the formal, exclusive nature of the academy, where so many PIs make their homes.

The work of PIs can be found in a variety of social-media spaces. A citizen searching for a public intellectual’s thoughts about the important issues of the day can find them in PIs’ blogs and

tweets, on PIs' Web sites, on Web sites such as "The Public Intellectual Project" (run by Canada's McMaster University), in podcasts featuring lectures by and interviews with PIs, in videotaped lectures posted to YouTube by organizations such as RSA and TED Talks, and on Facebook pages hosted by members such as "The Public Intellectual: Guru, Gadfly, and Gunrunner." PIs using these various social and other digital media to contribute to public discussion and enlightenment include academicians, journalists, social critics, political consultants, and media personalities as varied as Cornel West, Barbara Ehrenreich, Naomi Klein, David Frum, Fareed Zakaria, and Andrew Sullivan, among many others.

PIs Who Publish About Social Media

Not only do PIs use social media as forums for their ideas, in many cases, PIs blog, tweet, post, write, and/or speak publicly about social media and, notably, about the roles increasingly played by social media in political movements. The Arab Spring of 2011, for example, brought to the fore widely accessible arguments by PIs about the centrality of Twitter and Facebook in the processes of political organization and revolution in countries such as Tunisia and Egypt. Among the most prominent of these was "The Political Power of Social Media," an article published in *Foreign Affairs* by New York University Professor Clay Shirky. Shirky, the director of NYU's interactive-telecommunications program, as well as a frequent contributor to publications such as the *Wall Street Journal*, *Wired*, and the *New York Times*, might well be considered an exemplar of the 21st-century public intellectual.

Perhaps even more noteworthy is Nicholas Negroponte, author of the 1995 book *Being Digital*, and founder of both the Media Lab at the Massachusetts Institute of Technology (MIT) and *Wired* magazine, who speaks and writes extensively in scholarly and popular outlets about the power of social and digital media to change the world. Negroponte may be unique among PIs because he puts his money (and that of his supporters) where his mouth is.

As the developer of the One Laptop Per Child project, a philanthropic initiative that provides computers to children in the world's poorest nations, Negroponte is the driving force behind an

effort that has distributed laptops to over 2 million children in more than 40 countries—a public dissemination of not merely ideas but also the very tools necessary in the digital age to stimulate the development of and appreciation for intellectualism, public as well as private, around the globe.

Push Polling

Push polls are political polls through which the pollster attempts to impact the views and attitudes of respondents by pretending to ask survey questions. Unlike regular polls, which aim for randomization and are deeply concerned with

recording respondent data, push polls reach out to a large number of possible respondents, and are more concerned with spreading information than in gathering information. The subject of push polls may rely on innuendos, small bits of information from opposition research conducted by the campaign, or in its worst form, pure rumors. In any case, the information presented is misleading, and tends to work against the traditional democratic process. It is viewed negatively enough that both the American Association for Public Opinion Research and the American Association of Political Consultants have written policies barring members from partaking in the practice, regardless of the strategic advantages it may give them.

Push polling has been conducted since the advent of polling in one form or another. Yet in recent years, the practice has garnered significant negative attention and campaigns have veered away from the tactic. However, the development of social media has made push polling easier to pull off, with fewer reputational risks. No longer does one have to be as concerned with leading polls being tracked back to a campaign when they can be posted by anyone on any number of social media sites that are decidedly more difficult to definitively link back to a candidate or campaign.

In their most mild form, push polls simply remind voters of a particular issue that may have a negative connotation. For example, polls conducted by Republicans in West Virginia would often ask if individuals were aware that Robert Byrd had been a member of the Ku Klux Klan. While the information was factual, it was only included in polls in an effort to discredit Byrd and attempt to convince voters to not support him. More serious push polls will involve direct negative attacks on opponents, and rely on non-factual information. For example, a poll may ask: "If you knew that Governor Miller committed adultery, how would that impact your view of him?" There may be no proof of an affair, and the offending campaign can claim that they were just trying to anticipate how a scandal could impact the race, but it is clear what the motives actually are.

Sample size and poll length are two telling factors to distinguish push polls from traditional

polls. Real polls tend to use small, representative samples that allow for valid results, while push polls instead behave like traditional marketing efforts, casting as wide a net as possible. Since they are not concerned about the data returned, there is no need for push polls to be concerned with samples or respondents. Further, push polls are very short. They do not see the need to gather any type of background information, as they are only worried about pushing out a message to as many people as they can. Regular polls can go on for up to 30 minutes, and typically ask positive and negative questions about a plethora of candidates and issues. Most conclude with questions related to demographic information of the polled individual.

2000 Republican Presidential Primary

While push polls had been used for a long time in campaigns, they became the center of national attention during the 2000 Republican presidential primary in South Carolina. While not proven, it was strongly alleged that the Bush campaign had used push polling in an effort to discredit Senator John McCain.

Given the history of race relations in the southern state, it is of little surprise that the push poll had strong racial undertones. Voters were asked whether their likelihood of voting for McCain would change if they knew he had fathered an illegitimate black child. Thousands of voters received the call, and it was aided by the fact that McCain had previously adopted a Bengali girl. While it has never been definitively traced back to Bush, he had a history of push polling. In 1994, his gubernatorial campaign was accused of asking voters if they would be less likely to vote for Texas Governor Ann Richards if they knew her staff was dominated by lesbians.

On face value, the tactic of push polling is ethically questionable. Insinuating information as factual when it is not undermines democratic values and the processes of the country. At the same time, candidates play to win, and if push polling can help them do so, it is difficult to dissuade. With social media gaining more and more traction as a vehicle for politics, push polling has become easier to conduct. Given the lack of filters or control on what individuals post in a blog or on Facebook, candidates and campaigns can

present information by any number of means, and then permit it to spread like wildfire across the Internet. With no real way of tracing back to the initial information, campaigns are less likely to face the blowback that Bush did in 2000 in South Carolina.

While professional consultants and public opinion researchers are strongly urged by their professional associations to not partake in push polls, new media have allowed candidates and campaigns to stealthily utilize these tactics, without the need for consultant help. Even more concerning, however, is that average citizens can present push polls through online means without any affiliation to a candidate or campaign. This can adversely affect how the campaign is viewed by voters.

Conclusion

While push polling is not deemed legitimate or acceptable, studies show that it works. As a result, it is likely to continue plaguing American elections for the foreseeable future. States—especially New Hampshire—have begun taking legislative action to attempt to limit the influence of push

polling within their state's borders. Other states will likely follow. Push polls do not just mislead the public, they also misguide political system.

Quebec, Canada, 2012 Student Protests

From February to September 2012, postsecondary students in Quebec, Canada, went on strike. Students opposed the provincial government's plan to raise tuition over five years, from 2012 to 2017. The urban centers of Montreal and Quebec City saw the largest protests. On September 5, 2012, the government abandoned its planned increases, ending the strike. Social media played a central role in the protests as it was used for organizing and following marches, debating issues, critiquing the media, disseminating messages, and both making and breaking political careers.

On February 14, 2012, 11,000 students from Université du Québec à Montréal and Université Laval voted to strike against the provincial government's tuition increases. Parti Québécois Education Minister Line Beauchamp sought to raise tuition by \$325 each year from 2012 to 2017. Average Quebec undergraduate tuition fees were less than half the Canadian average of \$5,366 in 2012. As a result, Quebec has higher postgraduate enrollment (9 percent) than other Canadian provinces, and delivers high school's senior year and college's first year via inexpensive CÉGEP's (general/vocational colleges). This system, though praised for resembling European models of

postsecondary education, has caused Quebec to accumulate greater education debt. Attempts to cut \$103 million from postsecondary education in 2005 prompted students to strike for five weeks.

The University Student Federation of Quebec (FEUQ) and Broad Coalition of the Association for Student Union Solidarity (FEUQ) are the two largest Quebec student associations. The first weekend of the strike, FEUQ trained its delegates in strike workshops, including using social media. The original 11,000 students became an estimated 180,000 by late April. Participation ballooned to 400,000–500,000 people at a protest in Montreal on May 22, the 100th day of protest. Organizers proclaimed it the largest act of civil disobedience in Canadian history as people marched in violation of Bill 78, a law that banned protest within 50 meters (164 feet) of a campus and required police approval for public protest routes involving 50 people or more.

In February, student strikers shut down Montreal's Jacques Cartier Bridge during an afternoon rush hour. They also shut down the Montreal-bound ramp of the Champlain Bridge during a morning rush hour in March, leading to 100 arrests. On March 22, 200,000 protesters assembled in downtown Montreal. Spectators could follow the protests through Facebook, blogs, online videos, Concordia University Television (streaming online), and an Android application.

The protests resulted in occasional violence, with injuries suffered by both students and police, and thousands of arrests. In late April, protesters broke windows, vandalized artworks, and triggered fire alarms at Université de Montréal in an attempt to disrupt exams. In response to the growing violence, FEUQ asked the Broad Coalition of the Association for Student Union Solidarity (CLASSE), representing about half of the student strikers, to publicly condemn recent acts of vandalism so that student organizations could be included in government talks. CLASSE spokesperson and protest leader Gabriel Nadeau-Dubois stopped short of completely condemning violence by reiterating that students had the right to self-defense against acts of police violence.

On May 10, 2012, during morning rush hour, the Montreal Métro was shut down when

protesters targeted three subway lines with smoke bombs. The resulting confusion essentially crippled parts of the métro and left thousands of commuters stranded. Four suspects, three women and one man, were subsequently arrested for the smoke bombings. The four were identified through camera footage, and they turned themselves in. In addition to the May 22 protests of Bill 78, it was also during this month that talks between student groups and the government broke down when two different government proposals to increase tuition 70 percent by 2020 were rejected.

By late May, casseroles (French for “pans”) protests, where people march while banging on pots and pans, were occurring in Montreal regularly at 8:00 p.m. During this time, three Twitter hashtags (#ggi, #manifencours, and

Members of the student organization the Broad Coalition of the Association for Student Union Solidarity (CLASSE), which represented around half of the student strikers during the Quebec students protests of 2012, marching during the massive May 22, 2012, demonstration marking the 100th day of the protests in Montreal. Crowds of 400,000 to 500,000 people gathered that day, which some called the largest act of civil disobedience in Canadian history.

#casserolesencours) produced 700,000 posts in just a month. Social media prompted students around the world to march in solidarity, publicizing the time, place, and location of demonstrations and debated tuition increases, as well as discussing Bill 78, Premier Jean Charest, the police, and journalistic coverage of the events. Also in May, five university newspaper reporters (from Concordia University's *The Link* and McGill University's *McGill Daily*) posted on the Montreal Police Department's Twitter account (@SPVM) to secure their release when they were mistakenly arrested as protesters, despite holding press credentials.

In June a Montreal blogger known only as Anna argued that the English Canadian media were less critical of Bill 78 and were less sympathetic to the plight of the students than their French counterparts. Anna believed that limited access to French-language media was to blame. She in turn used Tumblr to create the site called Translating the Printemps Érablé. A dozen volunteers or so, including professional translators, posted translated French-language reporting, first-person accounts, videos, and editorials to the site in English. That month, the site registered 60,000 page views from 35,000 unique visitors. A Montreal Web designer bought the domain QuebecProtest.com and donated it to the project. "Maple Spring" (*printemps érable*) sounds like Arab Spring (*printemps arabe*) in French, plus both are activist movements fueled by social media.

Early on, protesters argued that Education Minister Line Beauchamp fueled the protests by dismissing them with a February directive for classes to continue, even as additional students voted to strike. Beauchamp's office was subsequently vandalized, and she received death threats. On May 14, Beauchamp resigned as deputy premier and education minister. Beauchamp stated that her failure to recognize the power of social media was her downfall, and that she resigned not because of violence, but because she was no longer part of the solution. Similarly, the Quebec government was criticized for overlooking social media. It took the government four days after Bill 78's passing to call a press conference to defend it, while student protesters

immediately critiqued the law and organized protests on social media.

FEUQ president and protest leader Léo Bureau-Blouin, however, became the youngest person (20 years old) ever to be elected to the Quebec provincial government under the ruling Parti Québécois in the fall 2012 election. He subsequently received threats and harassment on the Facebook page he used to communicate with his constituents from individuals upset that he had switched sides from protester to politician. Also, CLASSE spokesperson and protest leader Gabriel Nadeau-Dubois became a media celebrity during the protests. He became sought after as a protest advisor, conducting an Ontario university tour following the Maple Spring.

Even before September 5, the official end of the strike when the government abandoned its originally planned tuition increases, several post-secondary institutions had already returned to class, some meeting during August and on weekends to make up lost time. Despite calls for solidarity during the strike, roughly two-thirds of Quebec students, including many from McGill University, remained in class and completed their final exams. In spring 2013, Premier Pauline Marois participated in an education summit before introducing plans to increase tuition 3 percent each year until 2018, prompting students to return to the streets in protest.

R

Race/Ethnicity and Social Media

Early notions around the Internet were to create a digital utopian society absent of race; however, race and ethnicity are ever present in online communities, and in particular within social media. Since social media centers around interactivity and the exchange of information, the interests, and the identification of its users have become integral parts of engagement. With more than half of Internet users employing some type of social media, preference and practices differ between racial and ethnic groups. Race and ethnicity in social media is a rapidly growing field, looking at how specific groups utilize, choose, and appropriate social networking sites (SNS). Currently, Facebook is the dominating social media in the United States, but Twitter and Myspace have the most diverse users.

While Twitter is the second-largest social media employed, Myspace is considered a dwindling SNS; nonetheless, both provide a platform where an aggregate articulation of voices can interact online. Pinterest, Instagram, and Tumblr are noted as additional popular social media applications, but there are other social networking sites that garner millions of users that represent an array of racial and ethnic groupings such

as online forums, blogs, YouTube, virtual gaming, and virtual social worlds.

Social media engagement in politics, entertainment, and issues concerning specific groups has seen a surge of activity by nonwhites, establishing even more variety of online information and exchange. For instance, the 2008 presidential elections witnessed an increase in communities of color exercising various social media platforms to engage in political discourse, and the presence of black, Latino, and Asian bloggers is becoming more visible in the blogosphere. Whereas sites like Myspace saw a departure of white users, other racial and ethnic groups continue to use the site to articulate complex and overlapping interests that include identity and group belonging. At the same time, Myspace still serves as a vehicle to network through music via a diverse cultural exchange. Furthermore, blacks, Asians, Native Americans, and Latinos use social media to stay current on issues in their neighborhoods more than whites. In sum, social networking illuminates a burgeoning diversity.

Identity, self-presentation, and mobilization are salient themes in race/ethnicity discourse around social media. The United States is comprised of a large white population and principally operates from a white hegemonic cultural, political, and economic thrust. Although nonwhite populations outnumber whites when combined, and

Hispanics alone come close to being the most populous racial group, these groups are constructed and approached as minorities in every major institution. Social media allow racial and ethnic groups to establish an online identity prescribed by them; they also furnish a space where groups can connect and mobilize interests in ways that were previously difficult, especially for marginalized populations. Through social media, racial and ethnic groups have an opportunity to initiate agency while cultivating community and connecting with group members within relevant cultural frameworks.

African Americans

With more than half of black Internet users visiting a social media site at least once a day, African Americans are shifting the media landscape. Although African American households are less likely to own a computer or have Internet access at home, and possess fewer chances in accessing public broadband sites in their communities as compared to whites, their active participation on SNSs contributes to complicating ideas around online agency, accepted forms of communication, civic engagement, and public presentation. Blacks tend to use Twitter more than any other racial group. Research suggests that Twitter is a popular medium for African Americans because of its user-friendly and mobile-friendly capabilities. Twitter does not need access to the Internet to work; it is accessed via a phone with a text messaging function. On a cell phone, Twitter messages are designed in a style similar to that of texting.

Also, African American Twitter users favor entertainment and celebrity news, and often engage in public discourse with notable figures. In some ways, the practice of being involved in public discourse regarding famous personalities generates a status that appears intertwined with celebrity lifestyle; in other ways, it appears to position members of a marginalized group within a circle of power brokers. Additionally, African American interests are situated within national and sometimes international dialogue through the use of hashtags. Currently, African American topics are ranked as some of the top issues, obligating users to notice the critical interests and aspects of cultural perspectives in the black

community. Twitter use by African Americans has opened public discourse and a growing acceptance around the usage of African American communication and language. There has been an increase of cultural rhetoric found in the oral traditions of African Americans in Twitter text. Also, there are frequent occurrences of text that defies established grammar and vocabulary rules that is seen in African American communication, and is now captured in Twitter posts; it is being adopted into general communication habits.

Self-presentation centers black participation in social media. On sites such as Facebook, there are high volumes of self-portraits and pictures documenting the everyday life of black users. In the case of Instagram, an SNS that is employed by African Americans more than any other group, the picture presents the personal profile. Photographic agency is an important method to connect to friends and to establish an image that is user-generated, rather than a mainstream media representation. Belonging and community are recurring themes illustrated among black social media users. A study by Bun Lee showed that African American college students who had Facebook accounts mainly interacted with other African American friends, with a greater emphasis on staying connected to family and associates than meeting new friends, promoting a business, or using it as a source of entertainment. In addition, blacks use online forums catering to their issues and interests, specifically around being black. In terms of black bloggers, they disproportionately focus on political issues, along with an emphasis on encouraging racial group members to mimic their online civic engagement offline. However, relationships are the most popular topic for black online forums, followed by a focus on identity, heritage, politics, religion/spirituality, and women, all subsets of collective acceptance and community building.

Black SNS users have carved out a niche community on YouTube focusing on aesthetics, in particular, cosmetics and hair care. Black YouTube communities design cultural and relevant topics around the unique composition of skin and textured hair, especially around grooming hair that is not chemically processed. Tutorials and videos that cater to various aspects of beauty from the perspective of black people, especially black

African American girls at Holmes Elementary School in Liberty City, Miami, work with a laptop computer in January 2012. While there are lower rates of computer ownership and home Internet access for African American households as compared to whites, African American Internet users are extremely active on social networking sites, with over half using such sites once a day or more.

women, has led to the creation of an alternative forum addressing issues that mainstream fashion and beauty overlook, and that African American communities are attempting to resolve.

Perhaps the biggest misperception of black social media participants is the assumption that black people are a monolithic group. Although African Americans are the largest group of the black demographic in the United States, ethnic assemblages use social media to carve out alternative customized black identities. Black ethnic identity in the United States is an oft-ignored facet of black social media users that can explain how online identities overlap and sometimes clash. For instance, the Cape Verdean community employs Myspace to create online communities that are focused on connecting other Cape Verdeans within discourse around identity, especially in a hegemonic culture that clumps them into African American and Latino racial categories.

Hispanics/Latinos

Hispanics use social media more than any other group, and have started to close the gap in the digital divide by becoming increasingly engaged in social media. The average Latino using social media is between the ages of 18 and 29, English-dominant but bilingual, has some college experience or more, and was born in the United States. Though their participation shows visible generational gaps, Latinos use social media to integrate into American society while preserving ethnic heritage and establishing a distinct voice recognizing multiple ethnic groups. Microblogging and blogging are avenues that give voice to a population that exist in physical mass, but still push for more media visibility, political power, and agency. The celebration of heritage is a critical aspect of Hispanic people. At the same time, employing tools that strengthen the voices of Hispanics is important. Latinos are the second-largest users

of traditional online blogs, and edge out blacks and whites in Tumblr, a hybrid genre of blogging. Tumblr is a social media site allowing users to share all forms of content, thus making available a platform where the exchange of information is multitextured and provides different layers of experience and understanding.

Blogs provide an arena to articulate the various perspectives of Latinos and serve as an extension of Hispanic-centered news. English-speaking or bilingual Hispanics learn more by blogging or following blogs, and Hispanic bloggers are likely to focus on issues of immigration more than any other group. Additionally, blogging is a social media that captures the nuances of ethnicity in Latino culture. For example, black Latinos or Afro-Latinos dialogue around race, identity, and discrimination in their homeland and host country. These forums concentrate on the experiences of black Hispanics in South America while making efforts to fill the gap of Afro-Latino history by sharing historical and current information regarding African countries of which members are descendants. Activist and 2008 vice-presidential candidate Rosa Clemente frequently examines her black Puerto Rican identity through blogging. The blogs provide discourse, looking at how individuals can obtain multiple group memberships, but it also gives outsiders a purview into ignored populations in the United States.

Hispanics are the second-largest users of Twitter and Instagram, and are more likely to use Twitter, Myspace, and Facebook for individual recreational purposes. However, political activism and awareness is intertwined in their daily lives; therefore, these SNSs are used to mobilize around critical community health problems and political issues. Unlike African Americans, most Latinos are connected to other countries; therefore, they participate in transnational engagements through social media that help maintain family ties and friendships across borders. Spanish-language media play a critical role in the lives of Latinos; however, the young Hispanic population in the United States is beginning to rely on wireless devices for Internet, radio, film, and television content. Consequently, traditional media such as magazines, print news, radio, and television make use of interactive sites to establish a multimedia platform, plus recruit and retain consumers.

Asian Americans

Unlike other minority groups, Asian Americans have the highest adaptation of technology and have gained entry into the digital world. Since a significant number of Asian immigrants migrate from countries with sophisticated technology infrastructures, most already participate in an SNS that is indigenous to their country and meets the needs of staying connected to language, culture, and the people. Asian Americans are the most active in daily social networking, and spend more time on Facebook than the average American. A number of members of this demographic belong to another SNS similar to Facebook that is from their homeland; nonetheless, Asian American females are recorded as spending the most time on Facebook. While the self-presentation of other ethnic groups like Indians and Latinos tend to highlight their faces on profile pages, southeast Asians and east Asians who live in the United States de-emphasize their features and present limited or reserved emotional expressions.

Also, Asian Americans have been identified as visiting and spending more time than any other group on YouTube. Efforts to obtain celebrity-like status are best seen in musical performances. YouTube is also used as a site where east Asian communities around beauty are explored, especially in the area of cosmetics, fashion, and cosmetic surgery. On the other hand, Indian women use YouTube for hair care; much like African American women, it is SNS fusing ethnic-specific information around body imaging.

Navigating and negotiating identity and belonging in the United States is one of the main topics of online forums for Asian migrants. These niche SNSs are used as support systems. Indian diasporas create virtual communities that operate like online families, providing kinship and reinforcement. Also, there are numerous social media support groups for Korean and Chinese wives who migrate with their spouses to new terrain, and work through daily life challenges of cultural and language barriers. However, there are segments of the Asian American population that do not fit into the template of tech fitness. Overall, the heterogeneous demographic is homogenized in America, making negotiation even more difficult, but at the same time validating the necessity of social media.

Native Americans

Native Americans are among one of the last demographics in the United States to garner Internet access, yet native nations work for inclusion in the digital world and actively engage in social media by using it as a tool to strengthen tribal community, preserve and disseminate First Nation cultures, and ultimately develop native nations. Social networking activity among Native Americans focuses on tribal communication, community engagement, and the ability to maintain inter- and intra-tribal connections. Additionally, social media is used to provide Native American representation to mainstream America that is both favorable and contemporary. There are over 500 tribes living on sovereign territories that make up a population of three million native people in the United States. On most tribal lands, it is difficult and costly to acquire access to broadband, resulting in less than 10 percent of the population accessing the Internet.

Since the beginning of the new millennium, there have been concerted efforts to build a tribal-centric technology infrastructure. Once the Internet was put into place, Native Americans immediately became engaged in the digital world and social media. Native Americans blog, podcast, and employ social media sites such as Facebook, LinkedIn, and Twitter, but most usage is seen on radio-streaming and video sharing.

Tribal Web sites are used to keep Native Americans informed of tribe-specific activities, festivals, trade shows, and Native American news. They operate as social network portals, serving as a resource and site to gather and exchange information. These sites are used to disseminate information such as event postings and coverage, job announcements, and health and safety advisories. Some tribal sites blog, podcast, or provide music streaming, though it is not common. There are only two online radio stations that provide radio streaming on an interactive platform, but they have limited broadcasting capabilities. Also, Facebook is an avenue used by tribal councils and Native American organizations. Pages that have been established by various tribes connect members and supporters around current news and issues. In addition, Facebook is used as a site to announce political activities and advocate for the protection of native peoples and their lands.

The native gaming industry also galvanizes Indian casino owners through its Facebook organizational pages, while individual casinos advertise to non-natives about casino activities such as concerts and gaming promotions.

Video-sharing and radio streaming have been the most salient social media used by First Nation communities. Over half of Native American Internet users watch videos on video-sharing sites such as YouTube or Google Share. Streaming music is used as a way to exchange music while educating and preserving native cultures that are in some cases vulnerable to becoming extinct. Rez-Kast is a popular video-sharing media known as the Native YouTube. On one hand, traditional music and cultural videos are shared; while on the other, modern images, music, and videos provide outside communities representations of current native peoples in efforts to minimize an American hegemonic imagination that depicts Native American people in outdated and racist frames. Native Americans use YouTube as a format to provide alternative depictions of native people. Often, there is a focus on traditional images of Native Americans in tribal clothes and participating in traditional ceremonies; however, the use of YouTube puts Native Americans in a contemporary setting, and allows YouTube users to engage in discourse around current issues that are important to tribal nations.

Radical Decentralization

In keeping with its roots in pluralism, radical decentralization is not defined by a single historical moment, political movement, or author. Frequently linked to different, often incompatible aspects of current political, social, and technological context, radical decentralization has been put to use by a remarkably broad spectrum of movements and theories. From leftist political organizations in South America and the Occupy Movement to charter school reform and the Tea Party, and even extending into business and marketing strategies, there are few contemporary movements that fail to make reference to the notion of decentralized, community-based strategies of organization. As a political term, *decentralization* is most often understood in opposition to the standardization and hierarchical organization that has been increasingly associated with multinational corporations and the global market. All of the recent uses of decentralization are rooted in the new ecology of social media and its potential to replace such top-down political and social structures with a mass-based local framework.

MoveOn is one of the most important contemporary illustrations of this integration of politics and social media into an effective decentralized collectivity based on the widening latitude of technological communication. In an operational statement (“The Way We Work”) credited to cofounder Wes Boyd, MoveOn claims that it is an “experiment in radical decentralization.” As a key tenet of its organizational model, decentralization extends to every part of MoveOn’s process,

encompassing the social, political, and business dimensions of its operations. The “radical” element of decentralization in this model expresses the extension of this concept into every aspect of the organization, rather than a claim to radical social critique that has characterized earlier leftist movements, from Marxian to anarchist and agrarian collectives. This willingness to integrate business models and work within a state-oriented politics (as opposed to models based on social revolution) is one of the reasons for the wide appeal of MoveOn and its ability to use social media to integrate members from across the United States for concentrated and delimited projects aiming to shift state policy.

In *The MoveOn Effect* (2012), David Karpf calls MoveOn a “networked hybrid of organizational practices” that uses a variety of Internet-based strategies to bring disparate and nonparticipatory citizens into effective political movements. The decentralized structure of MoveOn keeps its operational costs low, allowing participants who rarely donate to larger, more centralized political organizations to become involved through small, sporadic donations. The consistency between these fundraising practices and MoveOn’s Internet outreach has brought radical decentralization to the fore as a key concept in discussions of political policy and activism. As a hybrid network, MoveOn exemplifies one of the most potent aspects of media-based politics because it illustrates some of the most effective strategies for changing the criteria of participation while multiplying avenues for self-empowerment.

Beyond MoveOn

The concept of radical decentralization has roots in Euro-American culture, extending back to a period before MoveOn and what Victoria Carty has called “cyberactivism.” The broader context of MoveOn’s commitment to decentralization comes out of series of debates in the late 20th century by influential social theorists such as Jurgen Habermas, Chantal Mouffe, and Ernesto Laclau. These debates centered on the role of the social sphere, in contrast to the political or private spheres. Various elements of radical decentralization come into play in these discussions as part of a larger set of strategies concerned with the waning of “communicative action.” As Habermas argues,

the contemporary period is characterized by the loss of action-oriented communication in a social milieu that would allow groups to form around issues and effectively act according to those responses. Social media have had a direct impact on the creation of a commons in which communicative action might be possible again, but it is not yet clear how the very notion of the commons will in turn change as a result. MoveOn signals one possible route, and other unpredictable realizations of new social community, like the radical movements connected to the Arab Spring and the Occupy Movement, will also likely continue to emerge. Part of this unpredictability comes from the other sense of “radical” implicit in the decentralizing process, which denotes a shift in what community is, and how it is shaped, in the new media ecology. Within the context of these new political movements, assumptions about leadership, intention, and organization are undergoing a notable metamorphosis, as self-generating communities and spontaneous action develop in ways that depend on communication technologies to an unprecedented degree. This shift has led to a renewed focus on the underlying principles, or the “micropolitics” of social interaction that extend beyond considerations of official political policy.

In *Turtles, Termites and Traffic Jams* (1994), Mitchel Resnick gives one of the first accounts of the uses of complexity theory for understanding how political and social decentralization might work. Stemming from the mathematical work of Ilya Prigogine, complexity theory in Resnick’s account argues that decentralization is not only possible, but is already operative in many facets of human culture, including politics. Today, there is complexity in typical elements of daily life such as voting patterns, shopping habits (like Black Friday), and traffic jams, and these randomized developments now fluidly extend into Internet trends on YouTube and Twitter. In the many subcultures of social networking, these patterns are not coordinated, but they nonetheless can emerge into fully formed positions with a tremendous potential for influence, such as the viral YouTube series *Vote Different*. Today, these social media play an important role in shaping political and social community that is “radical” in the sense of pre-existing and extending beyond official political culture. As a social strategy, radical

decentralization can thus be understood as a set of tactics that try to harness some of these elements of complexity for focused political ends.

Political Action

Faced with a growing symmetry between governmental organizations and global corporate interests, many activists have turned to local and autonomous strategies based on radical decentralization and the strategies of complexity theory. In the Americas, movements such as the Zapatistas and Abya Yala have redefined radicalism as an attachment to the land and the local community while embracing the use of social media to communicate and coordinate action, both locally and globally. In a very different way, the global hacking group Anonymous uses radical decentralization to maintain anonymity while launching coordinated attacks on targeted Web sites. Each of these groups shows an unprecedented willingness to allow elements of complexity to be integrated into their policies and practices through their use of social media. Outreach programs, fundraising, and catching the attention of global news media, for example, often depend on local videos and documents “going viral,” rather than moving through official channels. While the Zapatistas and Anonymous would define their forms of radicalism differently, today they are linked through common strategies rooted in a new context of communication and technology that allows for an unparalleled degree of decentralization within their radical programs.

New social media make decentralization a real possibility for a number of groups and movements at both a local and a global level. On the other hand, the uses made of social media and the strategic purposes of decentralization are widely divergent, and often depend on the way that groups define their form of radicalism. As a key example, MoveOn demonstrates the close relationship between emergent communications technologies and new social and political paradigms of participation, while interpreting radical decentralization in relation to corporate business models of nonhierarchical organization and a commitment to shifting official state policy. MoveOn’s commitment to influencing politics at the state level stands in marked contrast to other forms of decentralized social organization that

preexist the turn to social media, but which are now using these media to achieve a different form of radical decentralization that challenges the, state-oriented model. In the future, it is likely that radical decentralization and the growth of social media will continue to play a central role in both of these models of political and social change. At the same time, the parallels in their methods could also lead to a more fluid exchange and hybridization between these divergent interpretations of radicalism, generating new modes of social and political action.

Real-Time Communication Nodes

It is often noted that the speed of communication has greatly accelerated since the turn of the 21st century. It is less widely understood that the

most temporally significant shift in this period is not acceleration but instantaneous, "real-time" communication (RTC). Whereas previous modes of periodic/delayed communication (PDC) featured broadcast nodes monopolized by mass media conglomerates, RTC differs from these in almost every respect. Most importantly, it is distinguished by live temporality and peer-to-peer interactivity.

Political Effects

Certainly, pure, instantaneous, real-time communication never literally occurs. Similarly, the ownership of social media is no less conglomerated than mass media. But the experience of RTC as though it were financially unmediated, and the negligible degree to which it is temporally impeded, produces effects on political life that are worth considering.

One of the main reasons for these effects is that the commonly recognized governing institutions today derive from PDC, rather than RTC nodes, even if the former is increasingly defined by the latter. The modern state was founded, consolidated, and expanded through mass media nodes such as the newspaper, radio, and television over the course of the past five centuries. The 21st-century globalized economy and its institutional attendants, in contrast, derive from the Internet. To the extent that transnational capitalism recontextualizes and competes with the modern state system, it is largely the instantaneity and interactivity of RTC nodes that enable its success in doing so.

Economic Crisis Example

The 2007 to 2008 economic crisis is one example through which this can be understood. Beginning in the early 21st century, transnational firms sought real-time trading opportunities within the borderless, instantaneous rhythms of digital transactions. These efforts were buttressed by the enforcement power of transnational institutions such as the World Trade Organization (WTO) and International Monetary Fund (IMF). In contrast, the democratic mechanisms of representative states that might have regulated such flows continued to operate within the much slower rhythms established by PDC nodes. As a result, by the early 21st century, the upper reaches of

many nation states conformed to the temporal urgency of supranational decision-making bodies such as the IMF. While they otherwise might have restrained real-time trading beyond borders, now temporally subordinated states “could not effectively process the slower rhythms of the representative assembly, the election cycle, public policy formation and mediated public debate.”

This meant that the most important decision-making practices occurred at a supranational level in both political and economic domains, with significant local effects. For instance, the deregulation of global finance capital enabled the transnationalization and securitization of subprime mortgage loans within the United States. The result was that the originating lender was no longer at risk in case of default, while the lender's risk remained. The loans were then bundled, purchased, and traded through human-powered or algorithmic, automated RTC nodes on a global level. As such, the slower, controlled rhythms of democratic decision-making in PDC-based states were unable to regulate the real-time rhythms of global economic forces.

Shortly after the crisis brought forth by securitized lending, numerous American financial giants collapsed, resulting in an extended recession, followed by the state-supported restabilization of global firms engaged in real-time accumulation. In contrast, for citizens governed by states internally, the consequences of risk were generalized in the form of the “jobless recovery.”

Social Media Mobilization

As the employment crisis overtook the economic crisis in 2010–11, civil society actors began to mobilize RTC nodes in their own right to circumvent the slower, increasingly impotent rhythms of representative democracy in PDC-based states. Facebook, Twitter, and other social media users outpaced newspaper, radio, and television representations, mobilizing hundreds of thousands in the United States and worldwide.

As such, heads of state who had previously ruled through the control of PDC nodes were circumvented with livestreamed video and other instantaneous text and imagery from cellphones, laptops, and tablets, which relayed scenes of street battles, occupations, and other conflicts to the populace, even when the slower mass media

refused to cover the events. This intensified social media mobilization while at the same time suggesting an unmediated, directly democratic alternative to dictatorial and representative democratic states alike.

Because RTC nodes are experienced as both financially unmediated and temporally unimpeded, they tend to bring forth conflict with PDC-based states as well as the RTC-based supra-state entities that subordinate them. But politically speaking, social media is actually a form of mediation that, like any other, harbors potentially detrimental effects. If the real-time temporality and profit-based orientation of RTC remains unconsidered, reflex may replace reflection, and fragmentation may undermine consolidation. Civil society attempts to recast the tension of PDC-state and RTC-supra-state entities through a reassertion of the withering public sphere may flounder as infighting and unstrategic action takes over.

In the wake of the events of 2011, the decline of the Arab Spring and Occupy Wall Street movements raises this question, as do the reconsolidation of both PDC-state and RTC-supra-state modes of control. Mark Poster and Gary Hall are two analysts who have addressed this question, albeit in a different context.

For Poster, the destabilization of public/private distinctions brought forth by interactive RTC nodes disrupts prior notions of a public sphere through which the populace might redirect state policy. For Poster, the Internet is not a public sphere, but is a medium that might facilitate a new form of it under conditions that may not have emerged yet. Insofar as it contradicts the continuing profit orientation of most RTC nodes, Poster argues that peer-to-peer flesharing is one domain in which the emergent form of such a public sphere might be seen.

For Hall, the public sphere is a dead end: not only has it been outmoded by RTC, but it was always a fiction in the first place. Whereas the public sphere requires universality, Hall asserts that the internal pluralism revealed by social media demonstrates the deep contingency and plurality of society. As such, RTC necessitates a break with consensus and democracy. Because actors are always embedded within a specific media environment, which defines their capacities

and self-understandings, the conventional image of the autonomous, individual citizen is as much a fiction as the public sphere. The real contribution of RTC then, is to make visible what has always been the case. Only once this occurs, argues Hall, might we bring forth a new mode of “hypercyberdemocracy.”

psychologist Hermann Ebbinghaus, following a series of experiments that he performed on himself. It is complemented by the primacy effect; together, the recency and primacy effects constitute the serial position effect. Recency effect has since been expanded by several notable psychologists, and offers a number of implications for contemporary advertising, Web design, and political campaigns.

In 1885, Hermann Ebbinghaus published *Über das Gedächtnis*, which was later translated into English as *Memory: A Contribution to Experimental Psychology*. The book describes Ebbinghaus’s memory experiments and subsequent findings. Ebbinghaus was convinced that higher cognitive processes could be studied via human experimentation. This view stood in contrast to popular scientific opinion of the 19th century, prompting Ebbinghaus to conduct his memory experiments on himself. Realizing that his memory processes would be linked to previous knowledge and understanding, Ebbinghaus sought to delineate an easily memorized set of words that possessed no prior associations.

His solution was “nonsense syllables”: consonant-vowel-consonant combinations with no repeating consonants or prior meaning (e.g., YAT, PED, and KOJ). Ebbinghaus delineated 2,300 such syllables, which he drew at random from a box. After recording each nonsense syllable in a journal, he would attempt to recall them aloud. The results of Ebbinghaus’s experiments were limited by his decision to use himself as the only test subject, thus reducing the generalizability of his work to a universal population. Despite this limitation, Ebbinghaus’s experiments resulted in a number of influential findings regarding the cognitive processes of human memory.

One of Ebbinghaus’s most significant contributions to memory research was the serial position effect. The serial position effect states that recall accuracy considerably varies depending on the order in which material is presented to a test subject. The serial position effect is subdivided into two cognitive biases: primacy effect and recency effect. According to primacy effect, when asked to recall items from a list, people tend to remember the earliest items with more accuracy than middle-of-list items. According to recency effect, when asked to recall items from a list, people tend

Recency Effect

When given a list of items to recall, the recency effect reveals that people tend to remember the final few items of that list most reliably. The term *recency effect* was first coined by German

to remember the final items with the most accuracy of all. The reason for each of these effects has been highly postulated since their introduction by Ebbinghaus in the late 1800s. One prominent theory for primacy effect is that test subjects have more time to devote to the initial items in a list: the first list item is rehearsed, the second item is rehearsed along with the first item, the third item is rehearsed along with the first and second items, and so on. Consistent with this argument, the primacy effect has been shown to reduce when items are presented to a test subject more quickly; it increases when items are presented more slowly.

Several theories also exist to explain the reason for recency effect. One prominent theory for recency effect is that final items of a given list are still present in the participant's working memory, or short-term store (STS), at time of recall. This theory, however, fails to account for the long-term recency effect that has been observed during delayed recall. A second theory for recency effect is based on temporal distinctiveness. It is believed that a shorter delay between hearing and recalling a list item results in a more distinct memory trace to that item; thus, end-of-list items are more easily retrieved. Yet another potential theory for the recency effect is contextually based. According to this theory, the retrieval of items from memory is accompanied by, or encoded with, the physical and emotional context in which it was first committed to memory. For this reason, the most recent items of a given list will have a more similarly encoded context to that of the present moment. The most recent items of a list are therefore more easily retrieved from memory.

Since the time of Ebbinghaus's memory experiments, a range of notable psychologists have continued to study and expand upon his original findings, including William Crano, a distinguished professor of psychology at the School of Behavioral and Organizational Sciences; Bennet Murdock, an emeritus professor of psychology at Yale University; and George Miller, a founder of cognitive psychology. As a result, the recency effect has been shown to offer a number of implications for the fields of advertising, Web design, and political campaigns. Within the field of advertising, the order in which consumers are exposed to advertising messages has not only been shown to affect their purchasing tendencies, but also

brand recognition and brand loyalty. Thus, consumers are more likely to buy, identify, and display constancy toward items to which they have most recently been exposed. Recency effect also has implications for Web site design, with visitors showing an increased tendency to click on links at the end of a given list. Finally, voter appeals delivered closer to Election Day have shown to impact voting preferences more than those delivered further from Election Day. Such a reality highlights the import of political advertising in the final weeks, days, and even hours of an election cycle.

Redalert.com

Today, billions of people are using the Internet as an information and communication tool. The Internet has become a living organism, with

its online Web sites accessible from all parts of the world. Each day, numerous Web sites are dying or announcing they are ceasing to provide services, and numerous Web sites are born with the hope that they will be visited by many people. A Web site can be a search engine such as Google, Yahoo!, and Bing, an e-mail client, a social networking site such as Facebook, Twitter, and LinkedIn, or a newspaper. To operate a Web site, one should have a domain name, a Web site designed around a purpose, a Web server, and an Internet connection with feasible data speed that minimizes the congestion present in Web site traffic. Furthermore, this environment should be secured from hackers, denial of service attacks, trojans, worms, and other kinds of malicious software. In this respect, operating a 24/7 accessible Web site is not easy. Most Web site providers use Web monitoring services in order to maintain the continuity of their applications and services. The Red Alert Web monitoring service of the Keynote Company is one such service.

Functions

The easiest way of understanding whether a Web site is currently working or not is to conduct a “ping” test. If a URL address of the Web page that is pinged does not return a “destination host unreachable” message, this means that that Web page is currently working and accessible to users. Furthermore, one can see how fast the speed of the network connection established between a computer and a Web site is with a ping test. This simple Web site monitoring method can be done upon the user’s request, and needs to be run at periodic intervals in order to check a Web site’s availability. However, the Red Alert Web monitoring application offers more than just a simple ping test.

Red Alert automatically checks a Web site’s accessibility four times or more each hour (either in 5- or 15-minute intervals) over the course of a day and informs its customers about their Web site’s performance, accessibility, and connection speed via e-mail or cell phone whenever any alarm defined by the user is triggered. In order to minimize false positive responses, these alarms are triple checked by Red Alert, which means that the system attempts to reach a Web site or a network device connected to the Internet on three different

Internet connections, which are fully independent from each other in terms of Internet backbone network, local Internet service provider, and local Internet connection equipment. If the users of Red Alert have a firewall (traffic filtering system), they need to be sure about whether their firewall allows traffic from the Internet connections that Red Alert uses.

Unless Red Alert detects an error for a certain Web site or a device connected to the Internet using all three paths, it does not notify the owner of the Web site or the device about the error. A network device that is monitored by Red Alert can be a domain name server, a Web server, a secure Web server (serving Web sites starting with https://), a mail server, such as SMTP, POP3 and IMAP, an FTP server, and other kinds of devices accepting TCP/IP connections over the Internet. Red Alert can also detect network-related problems with its auto trace function. It stores trace routes for the Web site or the device that is monitored via each of the three fully independent network connections, both when an error occurs and after the error is resolved, so that a user may compare the trace route results during and after the error. Furthermore, its network gateway monitoring function allows users to understand at which point of the network connection the problem occurred.

File size checking is another useful function of Red Alert that checks the size of files retrieved from a Web server at certain intervals (four or 12 times per hour). Thus, it notifies users whenever the content of a Web page, for example, has been changed or modified. On one hand, a change or modification in a file may mean an error for a Web page. On the other hand, an unchanging file size may indicate that there is a problem with the page. Red Alert can also be used to notify users when the size of a file is not changed, or to help them understand whether a Web page is working properly or not. The size of a file usually requires frequent input changes over time. For example, the size of a database file that stores user’s information for a specified Web site frequently changes. In this respect, if Red Alert notifies users that the size of the file has remained the same since its last retrieval, this indicates that the Web page is not properly working.

Furthermore, Red Alert logs daily statistics about the site’s performance, as well as errors

it detects for the monitored devices. These daily logs can be accessed online by logging into Red Alert's Web site, or they are automatically sent to the e-mails of the list of people defined by Red Alert users. As such, it offers an important, on-the-ground type monitoring and management tool for social media political strategists and scholars.

Reddit

Reddit is a social news and bookmarking site that allows users to submit links to stories, pictures, videos, or any other Web content, and have other users either vote them up or down. When a link is upvoted enough, it reaches the front page of the site, and has the potential for a worldwide audience. Like other social news sites such as Digg, the structure of Reddit allows for the crowdsourcing of news and information by having users, not an editorial board, decide what will be the leading stories for readers. This can, and does, lead to highlighting news stories and events that might initially have a low profile but have the ability to resonate with readers.

Reddit was founded in 2005 by Steve Huffman and Alexis Ohanian, following on the heels of the Digg and Slashdot sites. Rather than focusing only on technology stories, as those sites tended toward, Reddit went for a broader audience. As Digg began to lose its user base with version upgrades and was eventually sold off, Reddit took the top spot for social news and bookmarking sites in terms of monthly Web

Reddit cofounder Alexis Ohanian speaking about the growth of the site on October 16, 2009. Nearly 2 million users follow Reddit's politics subreddit, and politicians including Barack Obama have conducted popular "Ask Me Anything" sessions.

traffic. Its motto is "The Front Page of the Internet," and it aims to work like a newspaper full of links to stories, videos, and pictures on the Web. Like other social news and bookmarking sites, niche audiences tend to congregate around particular topics. While a great deal of Reddit's content is made up of funny images and memes, robust conversation (via comments) can happen on particular "subreddits" or topic threads related to an individual topic.

Many of the most popular threads are political in nature, with the politics subreddit drawing almost 2 million subscribers. Not only are political stories routinely shared and elevated to the homepage through upvotes, but the user base has been known to engage in fundraising for specific causes, such as humanitarian relief after the Haiti

earthquake in 2010, and over \$500,000 in donations to DonorsChoose in response to a petition from comedian Stephen Colbert. Additionally, the entire site “went dark” and took itself offline for a day (along with Wikipedia and several other major Web sites) in protest over the Stop Online Piracy Act (SOPA) in 2012.

Like the Digg Dialogg series, Reddit has been host to “Ask Me Anything” (AMA) threads. Celebrities and politicians have been known to engage in a question-and-answer session with Reddit users. Ron Paul took part in a video-recorded AMA in 2009, and President Barack Obama famously spent time in an AMA session in August 2012 right in the middle of the Republican Convention. These events are designed to allow users to ask questions that might not be routinely asked in mainstream media interviews. Unfortunately, despite the democratic and crowdsourced structure of these events, the questions are still chosen by the individual answering, and a fair amount of cherry-picking inevitably occurs.

With the apparent demise of Digg, it appears that Reddit will now be the most heavily used social news and bookmarking site on the Web. The idea of socially curating news has spread across much of the Internet, just as collaborative knowledge production via sites like Wikipedia has generated a tremendous amount of informative content. There have been many changes to the Internet since the rise of Web 2.0 sites like Reddit, Digg, and Del.icio.us, the biggest of which is the emphasis on social networking sites like Facebook and Twitter. While social networking sites rely on a user’s social graph and the incorporation of particular brands and news outlets via “follows” and “likes,” the structure of social news sites like Reddit provide the possibility of a user encountering much more information from outside one’s social circle. Time will tell whether these structures will converge.

Remix, Political

Political remixes are a specific form of user generated content (UGC), usually published and shared via social media platforms such as YouTube and Vimeo. Such videos often remix different forms of political content with popular culture, and as such are regarded as a form of political and/or social protest that provides citizens with a tool for political advocacy while facilitating a platform for interaction and discussion. The convergence of popular culture and politics is a key element in this. The accessible content that is created by these particular forms of UGC is enabling citizens to produce as well as consume critical readings of their political and social environment. This in turn encourages and facilitates political and civic engagement.

Music

There are many different forms of political remixes. Autotuned clips, for example, are remixes that take original political video material, for example from a news source or a political speech, and transforms the original message of the main character via audio remixing or manipulation by autotuning (i.e., lipsyncing the main character to a different audio message). On February 2, 2008, for example, the remix “Yes, We Can” was widely circulated and became hugely popular (more than 24 million views). Distributed by voters (the Obama campaign had no part

in the creation of the video), this clip transformed Obama's Iowa primary victory speech into a song in which many artists participated, such as hip-hop artist will.i.am, actress Scarlett Johansson, and singer-songwriter John Legend. This remix inspired other remixes, such as "john.he.is" and "No, You Can't," in which 2008 American Republican presidential candidate John McCain is ridiculed. The political remix of George Bush singing to the lyrics of U2's popular song "Sunday, Bloody Sunday," published in 2006 by rx2008, is another example.

More recently, Obama can be seen rapping in "99 Problems." This political remix, released on September 28, 2012, by Diran Lyons, builds on rapper Jay-Z's original 2004 song "99 Problems," and shows Obama singing an adapted version of the song in which he talks about various issues relevant to his presidency and the 2012 election (the economy, protests, and the companies that helped him win the election in 2008) by stating that he "has 99 problems but Mitt's not one" of them (an alteration of Jay-Z's original lyrics). The video won first prize in the Pirate Flix Video Remix contest (curated by Cory Doctorow). Obama is known to be fan of Jay-Z, who had already performed an adapted version of the song in January 2009 as part of the Staff Ball, the last official event of Obama's inauguration, in which the singer tweaked the lyrics to "I got 99 problems but a Bush ain't one."

Video

Another popular format is videos that explicitly use and remix news and journalistic footage with images from popular culture. Elisa Kreisinger, who coedits politicalremixvideos.com, has created several political remixes that gained national attention in the United States. One of her best known remixes, *Buffy vs. Edward*, has been nominated for the prestigious 2010 Webby Award in the Best Remix/Mash-Up Category. By re-editing and recombining clips to create a new critical reading with material that is already familiar to her viewers (in this case from the popular television series *Buffy, the Vampire Slayer* and the successful *Twilight* vampire saga), Kreisinger aimed to create an alternative reading in which a "pro-feminist visual critique of Edward's character and generally creepy behavior" is given

through the eyes of *Buffy the Vampire Slayer*. In doing so, she exposes sexist gender roles and patriarchal Hollywood themes in a fun and accessible manner. This accessibility is achieved because, according to Kreisinger, she uses a visual language with which viewers are very familiar. In this way, popular culture is used to talk back to society, and can therefore be regarded as more than just entertainment.

The political remix video becomes a voice, showing the expressive power of this particular medium, which offers an instant political commentary and disseminates alternative messages to the mainstream media. The form of these messages, audiovisual material, is of special importance to younger generations who experience visual language almost as a native tongue, making interpretation more intuitive.

Jonathan McIntosh, from RebelliousPixels.com, created the much debated *Donald Duck Meets Glenn Beck* in October 2010. This political remix took him roughly three months to make. Most of the time went into researching which parts of the radio shows of Glenn Beck he could use as well as the Donald Duck episodes. He has said that he could not have done it without the extensive help of hardcore fans on either side as there is so much material available.

Donald Duck Meets Glenn Beck remixes the radio rants of the popular American radio host Glenn Beck with Donald Duck in the 1950s. Using Donald Duck as a proxy for Main Street USA, McIntosh aimed to reframe and recontextualize fragments of the pre-existing animation with pre-existing pop-culture meaning. His choices of both Donald Duck and Glenn Beck were not accidental. Next to being icons in popular culture, both portray institutional power structures. Furthermore, McIntosh chose this particular content remix to show how dominant ideologies are upheld within society by both the media and the public.

Similarly to Kreisinger, political remixes give him the voice to express his concerns and to urge others to have a critical eye when interacting with the media. It is therefore important to acknowledge the responsibility that comes with being a pop-cultural hacker and video remix artist to stay true and faithful to the original content while creating new and original media content that

offers alternative political, social, and cultural narratives.

McIntosh's remix caused some upheaval in the mainstream media because Glenn Beck reacted to the remix by accusing McIntosh of propaganda and of being funded by the very institutions he was attacking (which was not the case). *Vote Different* is another example of a political remix.

Conclusion

Creating a political remix can be a powerful way of participating in the political domain. Furthermore, it constitutes a political act: The creator is engaged in the topic, and is required to have at least some factual knowledge about the topic at hand. Furthermore, since digital video makes it easy to cut and paste, the skills needed to perform these actions have a rather low threshold (at least for people who are familiar with digital technology).

In this way, these acts of participation in the political arena signify how ordinary citizens can become active participants in political discussion by deliberating, reiterating, and remixing their daily supply of offline and online information. This critical re-use of media texts can then be seen as empowering citizens because it offers an alternative option for political participation.

Reporters Committee for Freedom of the Press

The Reporters Committee for Freedom of the Press is dedicated to preserving First Amendment and freedom of information rights for U.S. journalists across all forms of media, providing advocacy, free legal advice, support, and resources. Formed at the beginning of the 1970s—a time when U.S. media faced several government subpoenas requesting journalists to identify confidential sources—the organization advocates for media professionals and lawyers, in addition to the thousands who use its Web site. In fact, since its inception, the committee has been involved in almost every major case involving freedom of the press presented before the U.S. Supreme Court, including the *Nebraska Press Association v. Stuart* and *U.S. v. Moussaoui*, in addition to hundreds of cases at the state and federal levels. Even as the nature and forms of media continue to evolve, recognition and protection of basic press freedoms remain central to democracy.

The committee serves as the leading advocate for media organizations' cyberspace concerns, with a central objective of serving not only journalists, but also Congress, state and federal agencies, and academics. Among its many services are amicus briefs and statements of support for the right to freely gather and disseminate information across media; regional training seminars on the legal aspects of electronic reporting; fellowships and internships for media reporters and lawyers; free online publications and information on freedom-of-the-press topics such as reporters' shield laws, open government, and other issues; rapid responses to journalists' questions about media-law stories; a 24-hour legal-defense hotline for journalists and media lawyers; and a special events reporters hotline for journalists who experience trouble covering major news events like political party conventions, presidential inaugurations, and similar happenings.

The Web site includes press releases on freedom-of-the-press issues; information on media law topics such as libel, reporter's privilege, content regulation, prior restraint, privacy, freedom

of information, secret courts, and newsgathering; a *First Amendment Handbook* sponsored by the Gannett Foundation and the Scheide Fund; A *Digital Journalist's Legal Guide* to help educate media professionals and bloggers on basic media rights; *Open Government* and *Reporter's Privilege* guides, both broken down by state; a *Federal Open Government Guide*; and a magazine, *News Media and the Law*. Additionally, a "Press Room" page on the committee's Web site includes information for journalists on deadline or "in a jam." When law enforcement tries to block press coverage, journalists are advised to bring their government-issued photo identification, cash to post bond, and to clearly display press credentials.

These resources are freely available online, and/or are available for purchase at nominal cost. According to the Web site's "History" section, the 1970 case of *New York Times* reporter Earl Caldwell, who was ordered by a federal grand jury to identify his sources in the Black Panther organization, was the catalyst for the formation of the committee. Caldwell's situation quickly prompted a meeting at Georgetown University to discuss the need for reporters to receive help when their First Amendment rights are threatened. Included among the journalists who were pivotal in the organization's formation were Murray Fromson (then of CBS News and the committee's cofounder), Mike Wallace, Ben Bradlee of the *Washington Post*, Tom Wicker, Robert Maynard of the *Washington Post*, Gene Roberts, Eileen Shanahan, Anthony Lukas (then of the *New York Times*, and another cofounder), and Fred Graham of the *New York Times*. Fromson, in his reflections on the committee at its 35th anniversary, stated that he and Lukas also contacted Barry Kalb and Jim Doyle of the *Washington Star*, as well as Jack Nelson of the *Los Angeles Times*.

Also, according to Fromson, the committee officially organized on March 8, 1970, although according to Jules Witcover in a story about the committee for the *Columbia Journalism Review*, its origins can be traced to the Democratic National Convention in Chicago in 1968. It began part time with limited funds, but was later able to recruit staff and attorneys as funding came in from news organizations and foundations. During its early years, the committee was a plaintiff in several test-case lawsuits, including a

suit to access 41 million tapes and White House documents held by President Nixon.

Jane E. Kirtley succeeded Landau as executive director in 1985. Under her leadership, the committee began producing such comprehensive guides for reporters as *The First Amendment Handbook* and *The Open Government Guide*. Kirtley also started a legal fellowship program for attorneys interested in media law. During this time, the committee began an endowment that now amounts to more than \$2.5 million. Lucy A. Dalglish was the committee's executive director at the time of the September 11, 2001, terror attacks. During Dalglish's tenure, the committee became the country's top authority on efforts at news suppression. Publications begun during this time—Homefront Confidential reports and the Behind the Homefront Web log—are seminal documents on freedom-of-information issues post-9/11.

More recently, the committee has teamed with other media-related groups to protect source confidentiality for journalists and to monitor legislation affecting the public's right to know. Its amicus curiae briefs filed on behalf of journalists provide a forum for the committee to remain vocal about issues involving press freedom. Fromson, now a professor of journalism at the University of Southern California's Annenberg School of Communication and Journalism, also noted in 2005, on the occasion of the committee's 35th anniversary, that the American public's right to know was just as threatened as it was at the committee's inception. The committee states that no journalist has ever had to pay for its assistance in helping to defend their First Amendment rights. It identifies this fact as encapsulating the founders' vision, and as the organization's proudest achievement.

Reporters Without Borders

Reporters Without Borders (RWB) (*Reporters sans frontières*) is an international organization that promotes freedom of the press and freedom of information. Founded by four journalists (Robert Ménard, Rémy Loury, Jacques Molénat, and Émilien Jubineau) in France (Montpellier) in 1995, and registered as a nonprofit organization, it soon took on an international dimension and gained consultant status at the United Nations and the United Nations Educational, Scientific and Cultural Organization (UNESCO). According to its online mission, Reporters Without Borders:

Monitors attacks on freedom of information worldwide, denounces attacks in the media, fights censorship and laws aimed at restricting freedom of information, morally and financially assists persecuted journalists, as well as their families, and offers material assistance to war correspondents in order to enhance their safety.

The association currently has 10 offices and sections worldwide, supports a global network of 150 correspondents, and implements activities on five continents through its national sections and through close collaboration with local and regional press-freedom groups. Reporters Without Borders' primary means of direct action are appeals to government authorities through protest letters or petitions, as well as frequent press releases. The organization has gradually developed two specialized spheres of activity. The first is focused on Internet censorship and new media, and the other is devoted to providing material, financial, and psychological assistance to

journalists. Through members of its international network, RWB collects data and investigates issues of press freedom by region (in Europe, Asia-Pacific, the Middle East, north Africa, and the Americas). When violations become especially alarming, the association sends a team of activists to assess working conditions for journalists in a specific country. Based on its investigations, it releases annual reports on countries, as well as the Press Freedom Index.

The Press Freedom Index is an annual ranking of countries compiled and published by Reporters Without Borders, based on assessment of the countries' press freedom records in the previous year. It reflects the degree of freedom that journalists, news organizations, and netizens (cybercitizens) enjoy in each country, and the efforts made by authorities to respect and ensure this freedom. Reporters Without Borders also provides assistance for journalists and media personnel who are in danger. It provides money to assist exiled or imprisoned journalists and their families and the unsupported families of journalists who have been killed; to enable journalists to leave their home countries if they are in danger there; to repair the effects of vandalism on media outlets; to cover the legal fees of journalists who have been prosecuted for their writings or the medical bills of those who have been physically attacked; and on occasion, to provide bullet-proof vests for use by journalists.

Besides these activities, the association also launches advertising campaigns with the pro bono assistance of advertising firms to raise public awareness of threats to freedom of information and the press, to undermine the image of countries that it considers enemies of freedom of expression, and to discourage political support by the international community for governments that attack, rather than protect, freedom of information. For instance, in 2011, Ogilvy and Mather Dubai created a series of print ads for Reporters Without Borders as part of its annual campaign, *Censorship Tells the Wrong Story*. Each photo was altered using strategic pixelization to change perception and add new meaning. The campaign helped spark a worldwide discussion about the issue. It also generated more than 25 million hits, and won several awards, including the Bronze Press for Magazine Product and

Besides such work as its annual Press Freedom Index and its direct assistance to journalists, Reporters Without Borders conducts public campaigns to raise awareness of censorship and attacks on freedom of the press. The nonprofit created this outdoor display to bring attention to the plight of two reporters who had been held hostage in Afghanistan for over a year.

Service at Cannes Lion International Festival of Creativity 2011.

Over the years, Reporters without Borders has published several handbooks to provide assistance to journalists and bloggers, and to raise public awareness, including *Handbook for Journalists During Elections* (July 2012), *Guide for Journalists Who Are Forced to Flee Into Exile* (June 2012), *Handbook for Journalists* (April 2007, updated February 2013), and *Handbook for Bloggers and Cyber-Dissidents* (September 2005, updated in March 2008). For example, the *Handbook for Journalists During Elections* aims at helping journalists assume their responsibilities and successfully cover elections. It claims that for journalists working for media of every category (radio, television, print, and online), scale (local,

national, or international) and form of ownership (state-owned, privately owned, or community), journalists have to be able to give citizens the tools they need to understand their country, what is at stake in the vote, and to help them make electoral decisions.

In 2008, Reporters Without Borders launched its World Day Against Cybercensorship to pay tribute to all netizens who continue to express themselves freely, despite repression. On this occasion, the association issues a report on freedom of information in cyberspace and an “Enemies of the Internet” list that identifies countries that are censoring the Web and harassing Internet users. The list classifies a country as an enemy of the Internet because “all of these countries mark themselves out not just for their capacity to censor news and information

online but also for their almost systematic repression of Internet users.” In 2007, a second list of countries Under Surveillance (originally Under Watch) was added. Both lists are updated annually.

On March 12, 2013, Reporters Without Borders published a Special Report on Internet Surveillance. This report includes two new lists: a list of “State Enemies of the Internet,” countries whose governments are involved in active, intrusive surveillance of news providers, resulting in grave violations of freedom of information and human rights; and a list of “Corporate Enemies of the Internet,” companies that sell products that are liable to be used by governments to violate human rights and freedom of information. The five State Enemies of the Internet named in March 2013 were: Bahrain, China, Iran, Syria, and Vietnam. The five Corporate Enemies of the Internet named in March 2013 were: Amesys (France), Blue Coat Systems (United States), Gamma (UK and Germany), Hacking Team (Italy), and Trovicor (Germany).

Return on Investment

Governments and politicians are becoming fast learners of strategies for using social media to secure a significant return on investment.

Governments tend to determine whether or not an action yields a return on investment by measuring the effectiveness of that action. A return on investment in this case may be judged not necessarily by the increase in dollars based on an initial investment, but rather in an increase in the results that, taken collectively, represent a decrease in allocated dollars over time. Governments are increasingly delivering more effective actions through social media, and are achieving a great return on innovation and investment. E-government initiatives such as Government 2.0 (both a book and a description of governments’ digital efforts) are immediately recognized by citizens around the world who have come to trust the content of their local government Web sites.

In recent years, when private sector giant Amazon added e-books to its collection of texts, its total sales increased, and devices used to support the new texts became widely available and more sophisticated. This move increased its market return on investment by lessening the need for warehouse space for books, as well as by decreasing shipping costs for both Amazon and its customers. Although governments have not taken to writing whole novels for public consumption, the use of social media to inform citizens, highlight achievements, and warn of disaster or emergency is on a steady rise. The invention of social media options and methodologies from Twitter to Facebook and from text messages to discussion forums hold the promise of quick content related to investments and potential investments in social media by government. Social media users have managed to transfer social options for communication to even the virtual environment in an effort to stay well connected. Governments have paid attention. A visit to almost any Web site will reveal icons indicating the site’s connections to social media applications such as Twitter, Facebook, blogs, YouTube, Flickr, Foursquare, and in some cases applications like YouCut, which allows real-time public debate on issues related to government spending.

It would be a challenge to find a person, agency, entity, or government that would reject a positive return on an initial investment. In fact, the goal of investing is the hope that returns will yield a comfortable profit for the investor. The profits can be used as savings or as income to spend as

the investor would like. In a business, profits may also be a savings or may also be used as capital for reinvestment or as operational cash for buying equipment or performing equipment maintenance. Where some may not see a connection with social media and the notion of a return on investment, others see them as complex and interwoven. With the proper organizational intent, social media may be another tool for providing “virtual profit” for a city, state, country, or group of countries.

For governments, reallocation of resources can be human or monetary efforts to meet needs, and in the best of circumstances to obtain a significant return on investment. New efforts to devise strategic plans for information dissemination as well as the dissemination of public goods have become standard elements for government planners. Since 2000 one can see the addition of government Web sites and, with each new tweak of technology, the addition of more efficient ways of delivering content on those Web sites. The notions and approaches for accomplishing more is a major goal for adopting information and communication technology (ICT). ICT has been integrated in long-term plans by governments around the world. Adding social media to ICT creates the foundations of a network that can assist in informing citizens of important events or for use in disaster situations. Scholars, academicians, reporters, and the average citizen are target audiences for determining whether or not government ICT strategies that include social media for improving governing are working. From the executive branch to part-time city council members, innovation is part of the strategy for improving citizen delivery of public goods. Citizens can see these changes in the current environment, and visit a Web site to see the income dissemination of the latest stimulus package, as Americans were able to do in the first Obama administration.

In the early 1990s, conducting any type of business that involved government payments was done either in-person or by phone, mail, fax, or bank transfer. Today, it is common for citizens to go to a particular Web site to pay taxes or tickets, or renew car tags and registration. California manages the potential for long lines at its Department of Motor Vehicles by encouraging citizens to make an appointment online or by phone for driver's licenses. Future innovations may include

“live tiles,” whereby government Web sites would pull live information from social networks, the Internet, and government Web sites, and report them live on their Web sites.

Twitter Town Halls

A social media innovation that has shown huge returns on investment in time is the 140-character-limit Twitter Town Hall. Local politicians and government officials from various entities employ the use of Twitter to broadcast ideas, bounce off notions for government improvement, or respond to citizen questions. The use of Twitter Town Halls has become more prevalent in the past few years by U.S. Congress members, local officials, and even President Barack Obama, who conducted a Facebook Town Hall in his first term. What this demonstrates is the kind of environment social media needs for it to thrive. By its nature, social media expands in a decentralized environment. A decentralized environment is one in which central authority is spread over a number of regions, each specific to a particular need. In this case social media's decentralization lies in its expanse of smaller collectives or groups. Governments that recognize this can find similar ways to reach citizens through social media's decentralized structures that naturally form based on the “likes” of individual members. From the success that is immediately measured in social media, governments can assess the degree of the return on its investment based on the social media infrastructure. From these results, governments can adjust, add, or detract innovative and collaborative methods to maintain a healthy return on investment.

Security

Although governments have made substantial progress in the use of social media to effect a positive return on investment, still more is needed. If the current environment and past lessons are any indication of the role of technology, government needs to lead or develop in-time strategies for meeting the needs of the fast growing sector of social media changes. The network techniques that gather friends and family around an event, photo, update, or concert must be harnessed by governments in an effort to reach citizens and offer relevant services in the arena citizens have increasingly come to use. The most

important progress that government can deliver in association with developments in social media is the security element that many users in social media find at some level comforting and acceptable. The October 2012 theft of 3.6 million social security numbers from a South Carolina Department of Revenue database by a computer hacker may deter interested citizens invited to a Facebook or Twitter Town Hall sponsored by the state. Investment energies and resources used to secure a Web site that uses social media for a variety of reasons is a return on investment that will continue to give the state and its citizens' positive returns.

For any indicator related to measurement certain elements or components of that indicator are needed for a full understanding of its impact. Some components are more essential than others and some are more quantitative than others. What has become clear is that a positive return on investment as it relates to the use of social media hinges on issues of security. For governments to fully utilize the advantages of a decentralized social media of citizens using mobile applications (apps), security has to be one of the first concerns prior to implementation. Writings on the subject of security of this nature represent a majority of the narrative when discussing governments' use of social media. Additionally, calls from the Federal Trade Commission (FTC) have been consistently made to the federal government to ensure Internet privacy. Secure sites and platforms help to inspire greater citizen participation.

Transparency and Participation

Besides security, a description of the components of a return of investment include a few more formula elements. Taken in isolation they generate a measure that when placed on a continuum identifies the degree of return on the investment with the use of social media in politics and government. For example, greater transparency is achieved when using social media. Add to that the opportunity for communication with agencies, increased collaboration within agencies and with private entities, and the advantage of providing quick information to the public thereby saving time and money. What social media does easily within groups is something that governments can use for an increased return of investment.

The updates on information within disasters to a variety of social media users would produce a significant return on responses and help to identify public needs and disaster caution sites.

An essential return on investment of social media used by the government is the probability that citizen participation could increase. Public trust in government officials and institutions has remarkably diminished in the past three decades. Social media may not resolve this decline completely, but it has been shown to increase participation in virtual group settings, and may do likewise for government. The advantages and uses of Twitter and Facebook change each day. Already noted is the use of Twitter and Facebook Town Halls; additionally, Twitter and Facebook feeds can mobilize cities to deliver public services today when they are needed, and provide a concise platform for faster research.

The elements mentioned as part of a formula for measuring a return on the investment of ICT innovation are by no means all inclusive. If anything, technology will either eliminate, redefine, or combine components examined in this discussion. For solid change each entity will have to determine the extent and amount of social media essential for its citizens that will produce a positive return on investment. For this to occur, governments may have to abandon slower incremental change models and adopt the speed and application that social media provide their users worldwide.

Rich Media Ad

A rich media ad is an online advertisement that contains a combination of video, audio, text, and interactive features to reach an online audience. Rich media ads can contain video ads, video games, polls, music, text, images, and dynamically driven content that changes based upon the actions of each user.

Rich media ads enable users to click and interact with changing content present within the advertisement. In order to understand the functionality of a rich media ad, it is helpful to compare rich media advertising with more traditional forms of online advertising. In the example provided below, the differences between a rich media ad and a medium rectangle advertisement are outlined in order to provide a concrete understanding of how rich media ads include additional media types and interactivity.

The Client

Say a politician running for office in a major city wants to create an advertisement that encourages users to donate a small-to-medium amount of money to his campaign. He has purchased a medium rectangle 300 x 250 ad that runs on the side of a Web page, and has also purchased a rich media ad medium rectangle 300 x 250. The politician's objective is to show the audience his position on several items on the ballot and encourage campaign donations. Next, the concepts for each medium rectangle ad are outlined below in order to demonstrate the difference between the ad type capabilities to tell and show the users about the candidate's platform.

In a traditional medium rectangle advertisement, whether built with flash-based technology or HTML and JavaScript, a combination of text, images, and motion would be placed within the ad space in order to tell users about the candidate. For the medium rectangle ad, a picture of the candidate might be displayed within the ad, along with text and images related to the candidate's stance on particular local issues. The medium rectangle ad could include a "click to donate" button that encourages users to donate to the campaign. By clicking the "click to donate" button, users would be taken to another site to make a contribution to the campaign.

Rich Media Ad

In the rich media ad, the candidate can show the users more about his or her stance on political issues with a combination of video and audio embedded within the rich media ad. In addition to the text on the page that shares more information, users can click on a video to see and hear more about the candidate's position and policies. Additionally, rich media ads can be configured to expand out of the 300 x 250 space and create an overlay over the content on the page in order to use even more of the screen space to display additional information.

Rich media ads respond to the actions of the users, allowing the ad to expand to display a larger video or game that can be clicked by the user to learn more about the candidate. Similar to the medium rectangle, the rich media ad would also contain a "quick donate" button to allow the user to donate to the campaign at any time during the advertisement. However, instead of taking the user to another page, it is possible to embed the "quick donate" feature securely within the ad so that the user is not taken to another location or page. The rich media ad could also contain a poll or survey that asks the user to click on the issues that are most important to him or her and the appropriate responses or videos related to the issues could then be loaded into the medium rectangle.

Rich media ads provide additional user interactivity options, and also enable clients to embed videos, audio, polls, and games into the advertisement. Additionally, multiple videos and playlists of content can be embedded within the rich media ad, bringing a stream of dynamically driven content to the user, depending upon whether or not the user clicks on the ad to interact with it. Rich media ads take advantage of the content interactivity that online advertising affords, and include ways for users to click and interact with traditional advertising in new and unexpected ways.

RightOnline.com

RightOnline is a nonprofit organization that operates under the management of the Americans for Prosperity Foundation (AFPF). The purpose of this project is advancing prosperity and liberty by encouraging and promoting greater online citizen participation. It hopes to provide leadership, train volunteers in grassroots organizations, and impact public policy. RightOnline favors and supports the notion of free enterprise and limited government. It hopes to utilize continually advancing technologies in order to impact government at the local, state, and federal levels. RightOnline encourages supporters and volunteers to use blogs, videos, and other social media Web sites to help promote conservative interests and candidates.

RightOnline was first established during the summer of 2008, when more than 600 people, many of whom were activists and bloggers, attended the first RightOnline Conference in Austin, Texas. Every year since then, hundreds of citizens, along with media experts, technology experts, and messaging experts come together at RightOnline's annual conference. Speakers, presentations, workshops, training sessions, and breakout sessions are part of each RightOnline conference. Since 2008, many notable individuals have attended these conferences, and have even served as keynote speakers, including former Alaska Governor Sarah Palin, author Scott Rasmussen, writer S. E. Cupp, and economic consultant Arthur C. Brooks. Besides Governor Palin, numerous other members of Congress and/or well-known individuals with presidential ambitions have attended and spoken at RightOnline conferences throughout the years.

RightOnline's reputation and connections can provide politicians (normally Republicans) a base of conservative support with those who favor limited and open government. Its annual conference has been held in a different location each year in an attempt to draw more supporters and volunteers; so far, conferences have been held in Austin, Texas; Pittsburgh, Pennsylvania; Las Vegas, Nevada; Minneapolis, Minnesota; and Orlando, Florida.

RightOnline has grown in both size and influence since its inception in 2008. In 2011, more than 1,000 people attended the annual conference, and RightOnline conferences are now covered by national media outlets including the *Wall Street Journal*, the *Washington Post*, the *New York Times*, C-SPAN, National Public Radio, and other local and national news organizations. RightOnline has connections to state and local-based grassroots organizations; many of these organizations share RightOnline's goal of an educated electorate that will participate in their government using new technologies and online capabilities, presumably with a conservative edge.

RightOnline works closely with its parent organization, Americans for Prosperity Foundation (AFP). The AFP was established in 2004, four years before it initiated the RightOnline project. The AFP works in two main capacities: education and advocacy. While it is in favor of free enterprise and limited government, one of its main concerns is economic policy. The AFP fights for an individual's right to economic freedom by battling potential tax increases and by encouraging policymakers to "eliminate waste, fraud, red tape, and governmental abuse." The AFP hopes that these conservative practices will encourage a free market economy, allow individuals more economic freedom, and promote an environment conducive for new businesses to be started and expanded. Besides economic freedom, the AFP also advocates for judicial fairness.

The AFP relies on active citizen involvement and monetary tax-deductible donations in order to operate on a day-to-day basis and to fund and organize larger-scale projects, such as the annual RightOnline Conference. The AFP has a total of 1.8 million members across the country, with state-level organizations in 34 of 50 states.

Over 90,000 individuals have contributed to the AFP since its inception, with about \$14.5 million donated in 2008 during the presidential election. Besides simply contributing to the AFP, donors also have the option to direct their funds to help RightOnline and its annual conference.

Robin Hood Foundation

For over 20 years, the Robin Hood Foundation, a charitable organization, has assisted New Yorkers in their fight against problems associated with poverty. The foundation is based upon the notion of venture philanthropy or free-market charity, combining investment principles with philanthropy. Founded in 1988 by hedge fund manager Paul Tudor Jones, the Robin Hood Foundation works with more than 200 nonprofit, poverty-fighting, charitable organizations located in New York City. In addition to the Robin Hood Foundation assisting poverty-fighting organizations monetarily, it also works closely with grantees to help make their programs more effective. Through the use of

social media, donors and grantees can instantaneously follow the organization. The Robin Hood Foundation uses Twitter, Instagram, Facebook, Google+, Tumblr, Foursquare, and newsfeeds to attract donors and potential grantees.

There are over 1.8 million people in New York City living below the poverty level, in one of the world's richest cities. The Robin Hood Foundation finds and funds programs that help alleviate poverty, making a positive impact on the lives of those in need. The foundation's board pays for all fundraising and administrative costs, making the donations amount 100 percent. The foundation says that poverty comes in many forms, affecting the body, the mind, and life opportunities. For instance, approximately one in six New Yorkers rely on emergency food daily, over 40 percent of New York's public school students will not graduate on time, and 350,000 people look for work daily. The chair of the board of directors, Lee S. Ainslie, says that the Robin Hood Foundation's goal is to deliver the highest return on every dollar.

According to the foundation's Web site, the advisory board is comprised of experts, industry leaders, and inspiring thinkers who assist with defining goals and objectives for the foundation. The foundation has granted more than \$146 million to fight poverty, identifying the most effective organizations that combat poverty. The foundation also invented a metrics system used to evaluate where its grant money should be spent, evaluating programs to compare benefit-cost ratios. The Robin Hood Foundation's Web site states that their innovative methodology compares the poverty-fighting values of any two grants, regardless of their purpose. The foundation monetizes the immediate outcome, estimating the benefit to poor people in each dollar it gives. The methodology allows the foundation's staff to evaluate every dollar that is distributed to its grantees in the following program types: job training and economic security, early childhood and youth, education, and survival.

The metrics translate the outcome of a program, aggregating its benefits into a single number. Additionally, the metrics provide a diagnostic tool to assist with identifying and evaluating potential problems and common attributes among the most successful grantees. The Robin Hood Foundation

Comedian Seth Meyers from Saturday Night Live greets donors at the annual Robin Hood Foundation Gala in New York on May 9, 2011. The foundation boasts a 15:1 return on investment dollars.

acknowledges the imprecision and incompleteness of current estimates, stating that estimates are not final and metrics are constantly under revision. Numerical calculations and the program officers' detailed expertise are used to make the final grant-making decisions. Third-party evaluation of these programs also guarantees the foundation's accountability.

The foundation's success is attributed to its metrics and sound business principles. Its Web site states that like a financial manager, the foundation chooses investments to maximize profits—a 15:1 return on the investment dollar. Executive Chairman of Google Eric Schmidt states that there is no foundation that is more effective than the Robin Hood Foundation. It is among the largest

private funders of food pantries, soup kitchens, homeless shelters, job programs, and public charter schools.

Through the use of social media, the foundation is able to spread its message, connecting potential donors and grantees to its online platform. The various media tools allow the foundation to instantaneously keep donors informed while sharing information to potential donors and grantees about its charitable contributions. Founder Paul Tudor Jones changed the face of philanthropy by making nonprofit organizations answer to their donors. Recently, the foundation announced on May 15, 2012, that it is partnering with the X PRIZE Foundation.

The partnership is launching a series of incentivized prize competitions, engaging people globally to find solutions to problems of poverty in New York City and around the world. The X PRIZE Foundation seeks innovators from various disciplines globally to create and inspire “radical breakthroughs” to benefit humanity, competing for a prize of nearly \$1 million. The Robin Hood Foundation is the largest private poverty fighting organization in New York City, raising \$19 million for its Robin Hood X PRIZE, along with \$38 million for its day-to-day programs.

Rock the Vote

Now in its third decade, Rock the Vote was the first organization to try to leverage the power of celebrity and social marketing to increase youth participation in electoral politics. Rock the Vote and similar programs incorporate youth culture as a central part of their communication strategy in the belief that by changing how young people think about voting—building positive associations and depicting it as a necessary rite of adulthood and citizenship—they can also transform how people act.

This strategy builds on insights from social psychology, in particular the idea that perceived norms influence behavior, and that by changing perceptions about political engagement, one may significantly change the numbers of youth participating in the political process. The effectiveness of this strategy has often been called into question, however, as the proportion of votes cast by young voters has not substantially increased over time, and the effects of exposure to youth-oriented campaign communications are difficult to quantify.

Nonetheless, Rock the Vote has made other contributions to political culture. Though Rock the Vote made its debut in 1992 in the early days of the Internet, the MTV-funded initiative pioneered several of the social and peer-to-peer marketing practices that are now common practice in the age of Facebook, Twitter, and other online networks. The significance of the organization should also include its contributions to a broader trend in American politics, as new communication technologies have become integral parts of campaigning.

History

Recognizing that declining voter participation rates have been driven in large part by shifting demographics and a growing young adult population, Rock the Vote debuted during the 1992 U.S.

presidential election season, when voter turnout rates were approaching an all-time low. Unlike traditional civic engagement initiatives, the program's sole purpose was to target the growing, but disengaged 18-to-24-year-old portion of the electorate. Rock the Vote is perhaps best known for its celebrity involvement. However, its program has always included targeted voter registration drives employing person-to-person contact and direct marketing, as well as an awareness campaign anchored by television spots. At launch, during the Bush–Clinton presidential election, the public service announcements featured an intentionally diverse group of prominent musicians working in a variety of popular musical styles. These performers included R.E.M., En Vogue, Aerosmith, Queen Latifah, Eddie Vedder and many others. In keeping with its demographic focus, the ads appeared on national cable and broadcast networks with high youth viewership, including MTV, VH-1, and Fox.

Outcomes

Although Rock the Vote has always enjoyed high visibility and name recognition, its effectiveness in achieving its primary aim of increasing youth voter turnout is less clear. From its inception, the initiative faced several barriers. The most significant limitation is that voter interest and turnout are driven primarily by both individual-level and societal circumstances that cannot be controlled by a communication campaign. For individuals, attributes like partisanship, generation, and life stage (whether one is in school, raising children, or in retirement, for example) matter most. At a societal level, it is the perceived state of the nation—the health of the economy and whether the country is at war or at peace—that determines political interest and participation. Compared to these considerations, the influence of communication campaigns is relatively weak.

The Vietnam War, for example, was influential on both levels. It helped to shape a baby boomer generation that would remain politically active throughout their lifetimes, and created an issue that polarized the country and drove people to the polls. Similarly, in 2004, dissatisfaction with the Iraq War also increased activism and participation among citizens of all ages. As political scientist Thomas Patterson and other scholars has noted,

2004 turnout was the highest that the country had experienced since the 1968 presidential election. Consistent with this tide of enthusiasm, voting among those less than 30 years old increased by 4.6 million, the largest gain since 1972, when citizens aged 18 to 21 were first allowed to vote. Nonetheless, since interest was also higher with older voters, the share of the votes cast by citizens less than 30 years old did not substantially change. Conversely, in 1996, four years after the inaugural Rock the Vote campaign, an unprecedented 60 percent of college-aged voters stayed home on Election Day. This lack of interest among young voters was consistent with larger patterns as a recovering economy boosted the incumbent and a third-party candidate weakened the opposition. The result was little interest in the election across the board. Despite the context, however, when youth voter participation reached a new low, many analysts declared Rock the Vote to be a failure.

Another challenge that Rock the Vote faces is that research on voter turnout shows that interpersonal interaction is far more influential than the mass forms of communication that are Rock the Vote's most prominent components. Face-to-face contact has been found to increase participation by as much as 8.5 percent and telephone contact has raised voter participation by 5 percent. Rock the Vote is unlikely to have impact of that magnitude.

A number of scholarly studies have measured Rock the Votes' effectiveness. Research conducted during the 1996 presidential campaign showed that television viewers who lived in areas in which Rock the Vote television commercials ran and who received Rock the Vote mailings were more likely to vote in the election. Voter participation rates increased by the greatest percentage when accompanied by direct mailers encouraging recipients to pledge to vote. In addition, the percentage of 18-to-24-year-old voters in presidential elections has substantially increased from the low of 40 percent in 1996 to a high of 48.5 percent in 2008. Other studies, including the work of public opinion researcher Carroll Glynn, have shown that when opinions about the importance of voting and civic responsibility are communicated by close family, friends, and peers, these can become internalized as norms, and those internalized norms may lead to increased rates of voting.

As a result, despite the inherent challenges, there is evidence that Rock the Vote has been influential. The organization may succeed in helping to shape the communication environment in which youth are more open to the idea that voting is an important responsibility.

RSS Feeds

RSS feeds is the abbreviation for rich site summary feeds, also commonly known as really simple syndication feeds, and refers to documents of a specific format (RSS) that are consistent, machine-readable, and are shared by Web sites through different applications. These documents are made of blog entries, news headlines, audio, and video, and include full or summarized texts, links to the sources of contents, plus metadata such as publishing dates and authorships.

The purpose of RSS feeds is to deliver frequently updated content to people who subscribe to this service. RSS feeds are distributed in a standardized format, typically HTML (Web page content) and include links to Web pages or other digital media. The process of transforming different types of content in the same data format and licensing contents of a Web site to other sites is known as syndication. Content is classified and aggregated by topics in one place and then sent to subscribers who requested to receive updated information on the chosen topic by their chosen Web sites. The process of sending selected contents directly to a specific subscriber is known as "feeding," and the aggregated content is called an RSS feed.

In order to receive RSS feeds, Web users need to register by clicking a feed icon in a Web browser or in an organization's Web site, or by entering into the reader the feed's uniform resource identifier (URI), which is a string of characters used to identify a name or a resource. RSS feeds can be read using specific software called an RSS reader, feed reader, or aggregator. RSS readers can be Web-based, desktop-based, or mobile-device-based. The most popular Web-based aggregators are My Yahoo!, Bloglines, and Google Reader; and desk-based aggregators are Amphetadesk (for Windows, Linux, and Mac), FeedReader (only for Windows), and NewsGator (for Windows, but integrated with Outlook).

One of the advantages of RSS feeds is that they allow subscribers to stay easily informed because they receive new content from the Web sites they are interested in once these become available. Another advantage is that RSS feeds ensure subscribers' privacy. Subscribers are not asked to disclose their personal information or e-mail addresses when subscribing to a feed, nor when they want to unregister; this avoids potential threats such as spam, viruses, phishing, and identity theft associated with sharing e-mail addresses. To unregister, RSS feed subscribers need simply to remove the feed from their aggregator.

Because the main purpose of RSS feeds is to aggregate news, the most common feed providers have been news sites such as the BBC, the *New York Times*, Reuters, *USA Today*, and many others, but today, content providers for RSS feeds are more often commercial and nonprofit organizations, bloggers, and even people who use Twitter. Lately, RSS feed services have been developed to provide feeds without relying on a Web site.

History

The inventor of RSS feeds is considered to be Ramanathan V. Guha, a computer scientist at Apple Computer, who in 1995 developed a structure description language called meta content framework (MCF). Its main function was to structure and represent the content of Web sites in a much more sophisticated manner than using metatags. The creation of MCF was very important for the development of RSS feeds because the MCF system was the foundation for later experimental projects in news syndication. In 1997, the first model of an RSS feed was developed. At that time, the creator of MCF, Guha, had left Apple Computer for Netscape, a U.S. computer-services company, and together with Tim Brey worked to improve the MCF system by moving it to an XLM-based format. The XLM-based format became the system employed by Guha and Dan Libby to develop the resource description framework (RDF) site summary, which is considered the first version of RSS feeds. RDF site summary was released for use in the portal My.Netscape.Com in March 1999. A few months later, a new version of RDF site summary with a simplified format was produced by Dan Libby for Netscape.

Libby also changed the name of the service to RSS. Despite the success, Netscape decided to remove RSS support from its portal My.Netscape.Com in 2001.

RSS service continues to exist with the contribution of the RSS-DEV Working Group, a private, noncommercial syndication working group, and UserLand Software, a U.S.-based software company. In June 2003, a competing syndication format called Atom was created with the intent to overcome some of the limitations of RSS format. In the following years, subsequent updates and new versions of RSS software were released. Despite the emergence of Atom, most major companies are still using RSS format for news syndication.

Rumors

Rumors are an old communication phenomenon that has taken a new form in the digital era. Social media, with its quick transmission speed, dramatically escalates the spread of rumors. Social media have also been used to tackle rumors in crisis communications.

Rumors happen in all cultures and societies. Although there is no real consensus on the definition of a rumor, most researchers agree that rumors are information released from unofficial sources with little evidence or verification. Rumors' communication consequences are sometimes positive, sometimes harmless, and are probably harmful to

society or some individuals or organizations most of the time. During the fall of a senior official in China, Bo Xilai, in 2011, rumors were prevalent on the Internet in China, as well as in media and Web sites outside of China that were targeted to audiences interested in China. Those rumors sustained pressure on the Chinese government, which had traditionally held an authoritative political belief that critical information should be kept confidential. It was then forced to provide information about the issue to the public.

Some rumors can be vitally harmful to particular individuals or organizations. In 2008, one of South Korea's most famous actresses committed suicide in her apartment after bitterly critical, malicious Internet rumors surfaced about her. She had been accused of driving another actor to kill himself by pressing him to repay money she lent to him while he was in debt. This high-profile case motivated the South Korean government to more strictly enforce its real-name law passed in 2007, which required more than one million visitors to use their real identification information to register with about 150 popular Web sites. The law was struck down in August 2012, by a South Korean constitutional court, with support from free-speech advocates.

Rumors are also significant political phenomena in the United States. Most political rumors, such as the allegation that President Barack Obama has no U.S. birth certificate, and that his health care plan included a "death panel," were mainly passed around via the Internet. Social media hoaxes about politics, such as Bill Cosby running for president in 2012, and presidential IQ scores, are also popular.

Research

Although rumors may have thousands of years of history, formal research on the phenomenon only began at the start of the past century. Bernard Hart conducted an early psychological analysis of rumor in 1916, in which he studied rumors as they were transmitted through several rumor-mongers. He found that rumors were generated due to the inability of human beings to accurately observe and retain what happened.

Robert Knapp published a classic study of rumor psychology in 1944. He found that rumors could satisfy certain emotional needs

of a rumormongering community. Knapp classified rumors into three types: pipe-downs (or wish rumors) talked about things rumormongers wished to happen. Bogie rumors talked about pessimistic things that the rumormongers were afraid of happening. Edge-driving (or aggression rumors) were normally based on hatred of a certain group of individuals within a community.

Seminal research on rumor came in 1946 to 1947, and was conducted by Harvard scholars Gordon Allport and Leo Postman. In their article and book, they proposed a formula that is now well known: $R = i \times a$, where R means the spreading of the rumor, i means the importance of the topic of the rumor, and a means the ambiguity of the available information about the rumor issue. They also called attention to the motivations that backed rumormongering such as sex, anxiety, hope, desire, and hatred.

Ralph Rosnow and Gary Fine, in their book *Rumor and Gossip* (1977), found that rumor was a valuable information commodity in workplaces and personal lives. In 2007, Daniel Solove published the book *The Future of Reputation*, which discussed the spreading of rumor and gossip on the Internet from the perspective of legal studies. The author argued that, in addition to letting the law step in to protect people from the harm of Internet gossip, the setting of the Internet and social networking Web sites need to be changed so that people can easily avoid exposing their personal information to the world.

Creation and Spread

How are rumors created? They are created in two ways: accidentally or intentionally. Most rumors are accidentally created from misunderstanding of the information source in the previous step of the communication process. Communication research has confirmed that people tend to be selectively exposed to, understand, and retain information that is consistent with their pre-existing values and beliefs. Classic experimental research on rumor conducted by Allport and Postman, as well as Rosnow and Gary, has found that original information is inevitably distorted when it is passed to five or six pairs of ears. The missing information and distortion also occur in written and digital communications, or sometimes even in mainstream media

outlets. Regarding China's bullet train crash in 2011, a popular and respected newspaper, the *Beijing News*, initiated a rumor that the bullet train drivers were only trained for 10 days before they drove the trains. The rumor was generated because a reporter misread a story issued by the government.

Some rumors are intentionally created to help or hurt a certain individual or organization. Rumors have also been used as an ideological weapon in political movements. Researchers have found that almost all political rebellions or revolutions in Chinese history were led by rumors against the regime then in position. The Boxer Rebellion, a violent anti-West movement that took place between 1898 and 1901 in China, for instance, was found to use a variety of rumors to deify its members and demonize Western and Chinese Christians, maintaining people's trust, support, and loyalty to its political goal of driving foreigners and Christianity out of China. In every election in the United States, rumors thrive. While most of them are generated from misunderstanding and/or selective understanding in the communication process, some of them are created on purpose to serve certain political agendas.

What determines whether a rumor spreads? Allport and Postman have pointed out that the importance of the topic and the ambiguity of the available information on the topic are two factors determining how fast and how far rumors will be spread. Rumors can go faster and farther if the topic is important for most people, and if there is not enough information for people to understand or assess the situation. This basic law of rumor explains why rumors spread quickly after disasters, when people are shocked and anxious to know what happened, but no one can provide satisfactory answers.

The formula, however, may not be powerful enough to explain some phenomena of rumors. Examples include the case of the South Korea actress, where the topic is interesting, rather than important, as much celebrity gossip is, and cases in which the individuals or the organizations involved in the rumors provide refutation (leaving little ambiguity), but cannot kill the rumor. A revised formula is therefore proposed:

$$R = (F + S) \times (A/(I \times C)) \times P$$

The revised formula has three factors. The first factor contains *F* and *S*. *F* stands for the fun components contained in the topic. *S* means significance, which is close to the concept of importance in Allport and Postman's original formula. Most celebrity stories are fun topics; most of the things people talk about during or after a disaster are certainly significant. The fall of the senior official in China is both fun and significant for talkers. The second factor contains *A*, *I*, and *C*. The ambiguity factor in the original formula, *A*, is adopted but weighted by refutational information available (*I*) and the credibility of the source for such refutational information (*C*). After the Japanese nuclear crisis in 2011, people in China rushed to buy table salt because rumors arose that salt could help protect against nuclear radiation, and that because of the nuclear crisis, no clean salt would be available after the stock in the grocery stores had sold.

Scientists and government agencies made statements to stop the rumors but to little avail. People in China tend not to trust the government and experts during crises, as there is a long tradition of covering up crises and fooling the masses. Refutational information from a credible source, however, can immediately kill a rumor. A rumor that one of the most famous Chinese authors had died spread virally on Weibo, a Chinese version of Twitter, but stopped immediately when a popular journalist who was also a friend of that author wrote on Weibo that she had just seen the author. The third factor, *P*, stands for plausibility. The more the rumor fits people's stereotype about the individual or organization involved, or fits what people can see in their daily life, the more likely the rumor will be accepted and passed on. In the salt radiation rumor in China, many people reported ignoring official statements because they saw people in their communities frantically shopping for salt, and there were signs reading "no salt" outside of grocery stores.

Social Media

The Internet, and particularly social media, fuels the creation and spreading of rumors. Social media also dramatically change the traditional definition of rumor. In classic rumor research, rumor is normally defined as unverified information from unofficial sources communicated via word of

mouth. In the digital era, rumors are most conspicuously transmitted through social media, at a much faster speed and with a much further reach. Traditional word-of-mouth transmission may take a rumormonger a day to reach 10 people; social media enables people to write a message in only a minute or retweet one in a second, which can immediately reach about 100 people, the average number of fans for a social media account.

Traditionally, people join the process of rumormongering for three purposes: to express their anxiety about the uncertain situation, to exchange information, and for fun. The architecture and design of social media emphasizes the second function, and perhaps adds one more: to gain social status and power. In the social media world, having more fans bring more influence and power, as well as higher social status. A key to gaining more fans is to regularly update social media, perhaps multiple times a day, with interesting content. Rumors most often fall into this type of content. If appropriately tackled, research has shown that social media rumors also tend to disappear much quicker compared to rumors spread through traditional word of mouth.

Crisis Management and Disaster Relief

While social media has its negative effects in facilitating rumormongering, its role in tackling rumors in crisis communication, however, has also been noticed. In May 2011, the U.S. Senate Committee on Homeland Security and Governmental Affairs organized an ad hoc subcommittee on disaster recovery and intergovernmental affairs and published a document, "Understanding the Power of Social Media as a Communication Tool in the Aftermath of Disasters," based on a hearing. The document discusses the significance for people involved in crises and organizations coordinating crisis relief to use social media to provide necessary, timely information and reduce rumors. People may also use social media to seek help in a crisis. Research has shown that more than half of people would want to offer help, if they received such requests from social media.

After the 2010 earthquake in Haiti, the U.S. Department of Homeland Security launched the Haiti Social Media Disaster Monitoring Initiative to more effectively reach people involved in the recovery. The American Red Cross, Centers

Federal Emergency Management Agency (FEMA) staff conducting social media monitoring by responding to Twitter posts about Hurricane Sandy recovery efforts at the FEMA Joint Field Office in Forest Hills, New York, on January 9, 2013. A number of federal agencies have developed social media efforts to improve communication and combat unhelpful rumors during disaster situations.

for Disease Control and Prevention, and Federal Emergency Management Agency all launched social media to communicate more effectively during crises. When dealing with the aftermath of a tornado in its community, the *Tuscaloosa News* in Alabama used Twitter and Facebook to disseminate information, and used a Google docs spreadsheet to invite people to post information about themselves or missing loved ones. The newspaper also created a blog exclusively devoted to debunking rumors, with comments from witnesses as supporting evidence. A crime blog on the Web site of the newspaper that updated people with the latest reports of criminal activity was also widely read during the crisis.

Conclusion

How should one handle rumors on social networks? Research has provided suggestions that

are consistent with the rumor formula proposed above. Recommendations include constantly monitoring social media discussions, as rumors can happen at any time and move quickly on social media. The earlier rumors are noticed, the better their damage can be controlled. Establish credibility of the information source on social media long before rumors take place, and provide a large volume of correct information immediately and across many social media platforms when rumors appear.

Russia

The Internet and social media in Russia are quickly growing, but access varies by age, locality, and income. Russia is unusual in its ability to compete as a resource provider. Although online news is growing in importance, television remains dominant. Russians are very active social networkers, and this has facilitated protest and civic activism. However, state elites and their allies have also used new media to their advantage.

Estimates of Russia's online community vary because of rapid change and contrasting methodologies, so the data presented here is only suggestive. In December 2011, there were 61,472,011 Internet users in Russia, comprising 44.3 percent of the population. An estimated 50 percent use the Internet at least monthly, 47 percent at least weekly, and 38 percent on a daily basis. By 2012, Russia was Europe's largest Internet population, and sixth globally. Between 2005 and 2010, users who logged in at least monthly grew 266 percent, while daily users increased 469 percent. A 2011 Open Society Foundations study attributed this expansion to economic growth prior to

the 2008 economic crisis, economic difficulties associated with the crisis, and the emergence in 2008 of the "tandem," with Dmitri Medvedev replacing Vladimir Putin as president, and the latter becoming prime minister.

Demographics

Younger Russians access the Web in significantly greater numbers than their older counterparts. A second cleavage segregates urban inhabitants who have high-quality access to new media from small town and rural dwellers who do not. Although recent growth in Internet access is fastest outside of cities, Internet penetration in Moscow and St. Petersburg is greater than elsewhere. Infrastructure quality is another important factor. Broadband connections are rare, and are concentrated in cities. Despite high growth rates for digital media in other areas, it is not clear how soon the digital divide will disappear. Income also plays a significant role in limiting media consumption choices. Finally, locality and wealth shape new media literacy, so "unwired" communities have limited knowledge about new technologies and the opportunities/challenges they afford.

Global Presence

Russia's global positioning is novel in that Runet, the colloquial term for the Russian language Internet, is dominated by Russian, rather than American companies. In December 2010, the three largest Runet sites, Yandex.ru, Mail.ru, and Vkontakte.ru, were Russian. Yandex is the only comprehensive global search index, other than Google and Bing. Its 2011 Wall Street IPO raised \$1.3 billion. Russian companies have also made a mark internationally. The Russian blog provider LiveJournal.com has an important presence in the United States, while the social networking site V Kontakte.ru has 110 million users throughout eastern Europe. Finally, it is important to keep in mind (particularly when interpreting data) that Runet includes millions of Russian speakers who live outside of Russia.

News Consumption

National television, which the state influences directly and through self-censorship, continues to be Russia's most important news source.

While television viewership is falling, television news audiences remain stable. Large majorities consider television trustworthy.

Though trusting overall, young people aged 18 to 24 are less so (67 percent) than the population overall (74 percent). Print media is in decline, particularly with postcrisis cost-cutting measures. Audiences for broadsheets have dramatically shrunk, whereas tabloid readership remains stable. However, traditional media outlets, including those that follow state ideology, have established an online presence.

Online news is growing in importance. Audiences at the top Internet news sites and portals (e.g., Mail.ru/novosti.ru and Yandex/novosti.ru) rival those of the leading broadsheet dailies. Russian language social networks are the main news source for nearly 20 percent of 18 to 24 year olds. Also, 52 percent of adults use the Web to look for information on politics. In 2011, 31 percent of adults believed that the Internet is an “important source of political information” compared to 13 percent in 2007. The corresponding 2011 figure for TV was 80 percent, and 36 percent for radio. Among the total monthly Runet audience, 48 percent regularly read online news. For 12 to 24 year olds, the corresponding figure is 92 percent.

Social Networking

Russia’s social networking boom began in 2008. In 2012, Russia was estimated to have the fifth-largest social networking population globally (57.9 million). A full 92 percent of Runet users have at least one profile. In terms of time per user, Russians are the heaviest social networkers worldwide. In August 2010, 34.5 million visited at least one social networking site, spending on average 9.8 hours per month, versus the global average of 4.5 hours per month. Social networking occupies 40 percent of Russians’ online time. The average participant is young (75 percent between the ages of 18 and 24), educated (57 percent are university graduates), and enjoys a stable income.

Vkontakte.ru is Russia’s most popular social networking site and the top European site in terms of engagement, with a typical user spending 7.1 hours on it during September 2011. Facebook launched its Russian site in mid-2010, and was fourth in terms of popularity by the end of the year.

In 2010, Runet had 15 million blogs and time on blogs doubled over the previous year. The most popular blog host is LiveJournal.com, with 14.4 million unique visitors in December 2010. Approximately 22 percent of Runet users communicate in forums and chat rooms, 17 percent read blogs and forums, and 3 percent have a personal blog. Although the number of blogs is expanding, in 2010, the proportion of blogs with more than five posts and at least one update during the previous three months began falling.

Microblogging is also booming. The leader is Twitter, which was the fifth largest social networking site in December 2010, with 4.4 million unique visitors. Runet has more than 50 million videos. YouTube is the most popular video site, and is far ahead of its closest Russian rival, Rutube.ru. The average Russian user consumes 140 videos a month. Photo and video content is accessed regularly by 38 percent and 34 percent of Runet users, respectively.

Protest and Civic Activism

Social media plays an important role in facilitating protest and civic activism in Russia. These sites are a venue for expression and organization for marginalized groups such as migrant workers, sexual minorities, and the disabled. The Internet was the main vehicle for disseminating the video *Virgin Mother of God, Banish Putin*, a profane public prayer performed by the feminist punk collective Pussy Riot on the altar of Moscow’s largest church in 2011. By August 2012, one YouTube version had been viewed 1,162,007 times, receiving 7,774 comments, 8,100 “likes” and 2,322 dislikes. After members were sentenced to two years in a penal colony, Internet activism helped mobilize international public opinion to show support. The pornographic photo series “How to Snatch a Chicken” by the related political group War was also publicized through the Internet. Although edited from TV broadcasts, a video of Putin being booed by a boxing crowd in 2011 went viral, demonstrating his falling prestige.

The most well-known figure in Russia’s opposition movement, former Yale University World Fellow Alexei Navalny, rose to prominence by blogging about corruption and corporate malfeasance among Russia’s state elite. Navalny also

used traditional media, famously dubbing United Russia as the party of “crooks and thieves” on radio Finam FM.

In the wake of the fraudulent 2011 parliamentary elections, new media supported communication and coordination to organize public protest, most notably in Moscow and St. Petersburg. Despite frigid temperatures, crowds numbered in the upper tens of thousands. Survey data from Moscow’s Prospekt Sakharov demonstration showed that 56 percent of participants were 18–39 years old, 62 percent had university degrees, 46 percent identified as specialized workers, and 38 percent and 31 percent identified as “democrats” and “liberals” (in the European sense), respectively. Also, 37 percent and 31 percent discussed the elections through social networks and blogs “regularly” and “from time to time,” respectively; 56 percent and 33 percent had learned about the protests through “Internet publications” and “other Internet sources,” respectively.

Online news and short message service (SMS) contributed to mobilization during the winter 2009–10 rallies in Kaliningrad. In response, the presidential liaison for the region was fired. Later, Moscow did not renominate the governor to his post. Nevertheless, the free weekly newspaper *Dvornik*, with readership equaling 25 percent of the city’s population, played the leading informational role, and in-person grassroots activism was also important.

Not all protest using social media aims for systemic political change. In 2009, Novorossiysk police major Alexei Dymovsky addressed an online video concerning corruption and inefficiency in his department to Prime Minister Putin. In one day, the video received 300,000 hits and had nearly one million hits a year later. Dymovsky’s action was followed by immediate changes, resignations, and nationwide police reform. He was also fired and faced criminal charges for fraud. Although the latter were eventually dropped, he was detained over a month awaiting trial.

Although success has varied, social media have facilitated grassroots financing. In 2010, activists used Facebook and e-mail to raise \$6,000 to pay the fines of two curators accused of “inciting religious hatred” during the controversial art exhibit “Forbidden Art 2006.” Contributions

were collected in person however, and participation fell short of organizers’ expectations.

Social media have also supported charitable work. In 2009, popular blogger Natalya Radulova used her LiveJournal blog to raise \$7,000 in three days to pay for a Tajik girl’s cancer treatment. During the 2010 wildfires, activist Elizaveta Glinka used the online Ushahidi platform and SMS to help victims and volunteers coordinate relief efforts.

The Authorities

State elites are ambivalent about social media. They recognize their value for Russia’s development and international integration. Nick-named the “blogger-in-chief,” former President Medvedev demonstrated special enthusiasm for new media, creating a video blog, LiveJournal blog, Facebook account, and a Twitter account that boasts 1,421,663 followers. In 2010, Profi Online Research recognized him as Runet’s most popular blogger.

Medvedev has used the Internet to unveil domestic and foreign policy, and to promote policy discussions. Other officials have followed suit by creating blogs and Twitter accounts, and hiring content writers. In connection with police reforms, a dedicated Web site was created for public consultations concerning the draft bill “On Police,” receiving over 1.5 million visitors and 21,000 comments in five weeks’ time.

Yet, the leadership is apprehensive that new media could produce conflict and instability, threatening the political regime. To minimize foreign influence, the state-owned Sberbank has a golden share to block sales that exceed 25 percent of shares in Yandex, which is considered “strategically important.” Prominent Internet entrepreneurs also include regime loyalists. Since Putin’s re-election, more intrusive measures have been deployed. A new law allows officials to block Web sites without a court order. Russian Internet providers are also acquiring deep packet inspection technology, which facilitates Web site blocking and monitoring of chat spaces.

Finally, state authorities and their allies use new media to their advantage. During the elections, the Kremlin and its allies used the Internet to promote their perspective. Tweets from the U.S. embassy were countered with tweets from the Ministry of Foreign Affairs. When

prominent opposition figures came to meet American Ambassador Michael McFaul, a camera crew from NTV greeted them. The video *Getting Instructions from the New Ambassador* very quickly received over a million hits on YouTube, reinforcing the regime's preferred narrative that foreign powers were instigating protests to destabilize Russia. Compromising information was also publicized after Navalny's e-mail account was hacked. Finally, Ambassador McFaul has suggested that his private information had also been hacked.

Ryan, Paul

Paul Ryan is an American congressman and former Republican vice presidential nominee. Ryan was first elected to Congress in 1998. He is currently the Representative for Wisconsin's 1st Congressional District in southeastern Wisconsin, which lies on the border with Illinois to the south and Lake Michigan to the east. After redistricting in 2012, his district includes all of Kenosha County and Racine County, a large part of Walworth County, and portions of Rock County, Waukesha County, and Milwaukee County. Ryan was re-elected to his seat in the House of Representatives in 2012 with 55 percent of the district vote against Democratic challenger Rob Zerban.

Born January 29, 1970, and raised in Janesville, Wisconsin, Ryan attended college at Miami University in Oxford, Ohio. He double-majored in economics and political science, graduating with a bachelor of arts degree in 1992. During his studies, he developed a deep interest in the writings of economists Milton Friedman, Friedrich Hayek, and Ludwig von Mises. He was also influenced by the philosophy of novelist and philosopher Ayn Rand. At the urging of faculty members at Georgetown University in April 2011, he would ultimately reject Rand's philosophy on grounds of its atheistic underpinnings. Ryan, a devout Roman Catholic, cites medieval philosopher Saint Thomas Aquinas as a significant inspiration in his life.

Congressional Career

Currently an eight-term member of the House of Representatives, upon winning his seat in 1998, he became the second-youngest member in the House of Representatives at the time. A rising star among House Republicans for his conservative fiscal policy approach, in 2007, Ryan became the ranking Republican member of the House Budget Committee. When Republicans recaptured majority control of the House in the mid-term elections of 2010, Ryan became chairman in the 112th Congress. He is also a member of the House Committee on Ways and Means, and is assigned to its Subcommittee on Health.

Ryan has openly embraced social media in his political and personal life during his congressional tenure. In the 111th (2009–10) and 112th

(2011–12) congresses, he used Twitter hashtags such as #FullRepeal and the handles of Senate Majority Leader Harry Reid and Speaker of the House John Boehner to debate contentious issues. His personal account on YouTube, the Paul Ryan Channel, had 4,614 subscribers, 245 videos, and 2,259,378 video views in November 2012. He has embraced social media not only to debate congressional legislation and policy issues, but also in his daily life at home. For instance, he has posted personal pictures on Facebook of turkey hunting and other activities from his family life in rural southeastern Wisconsin.

National Commission on Fiscal Responsibility and Reform

In January 2010, President Barack Obama created a bipartisan National Commission on Fiscal Responsibility and Reform to address fiscal challenges in the United States. The national commission was created so that appointed members could identify, draft, and propose policies to address trillions in federal deficits and debt accrued over the last decade, and bring a consensus on fiscal sustainability. Ryan was appointed to the commission by the House of Representatives in early 2010.

The national commission was cochaired by former senator from Wyoming Alan Simpson, a Republican, and former Clinton administration Chief of Staff Erskine Bowles, a Democrat. The working group became known as the Simpson-Bowles Commission. Democrat Alice Rivlin, a former White House budget director in the Clinton administration and founding director of the Congressional Budget Office (CBO), was appointed to the commission by President Obama. Ryan developed a working relationship with her on the commission that became known in 2010 and 2011 as the Ryan-Rivlin plan.

The Ryan-Rivlin plan addressed health care, specifically Medicare, in the broader context of the fiscal reform intended to be tackled by the commission. Ryan and Rivlin developed a plan that proposed modifying certain aspects of the Medicare system in order to achieve fiscal stability in the United States over the long run. The plan fell apart on April 5, 2011. Rivlin was interviewed by *Politico* on that day, and a story ran online in which she was quoted as saying that she did not support

Congressman Paul Ryan at the press conference on August 11, 2012, during which Governor Mitt Romney announced his choice of Ryan as running mate in the 2012 U.S. presidential election.

that version of the Ryan-Rivlin plan that Ryan had been promoting to the press and on social media at the time. Almost instantaneously the *Politico* interview was shared by its readers across prominent social media including Twitter and Facebook.

Washington Post blogger and columnist Ezra Klein also interviewed Rivlin about Ryan's budget proposals on that day, and the interview was publicized by his social media outlets, with the interview running on his *Washington Post* "Wonkblog" on the morning of April 6, 2011. The *Washington Post's* page for Klein's interview with Rivlin concerning Ryan's fiscal proposals was enabled for online readers to share on social media venues, ranging from Facebook to Twitter and LinkedIn to StumbleUpon. Ryan ultimately voted against the final recommendations of the commission.

The Path to Prosperity

Ryan has utilized YouTube and Twitter, as well as other social media, to promote his Path to

Prosperity budget proposals from the House of Representatives. After the activities of the 2012 election, he had a following of 4 million on Facebook and 800,000 on Twitter. The House of Representatives Committee on the Budget that Representative Ryan chairs keeps Facebook, Twitter, and YouTube pages. The proposals are generally called the Ryan plan, Ryan budget, or Ryan proposals by social media as well as traditional media.

The official page of the CBO is enabled for online readers of Ryan's House Budget Committee reports to Tweet links to its proposals, such as on Facebook, as well as bookmark and share on Facebook, Tumblr, StumbleUpon, Google, LinkedIn, Myspace, Delicious.com, Digg, and Reddit. Ryan used his "Path to Prosperity" platform in the 2012 presidential election. He began tweeting again about his budget proposals in the House of Representative from the 112th Congress. The Path to Prosperity official page on the House Budget Committee's Web site featured Ryan's tweets embedded with a link above the tweets allowing readers to follow him on Twitter.

2012 Presidential Election

On August 11, 2012, Mitt Romney officially announced that his running mate in the 2012 presidential election was Ryan. This was announced to his supporters via an iPhone application, which while unique, caused some chaos. The application was known as "Mitt's VP," and a notification was pushed out to users of the application. Romney's campaign hawked the Mitt's VP smartphone application, promising to deliver the identity of his running mate first. In the end, some downloaders received the notification at about 7:00 A.M. Eastern time, more than eight hours after the news media had confirmed it was Ryan. Not all the application downloaders received the notice, and an hour after Romney issued a press release naming Ryan as his running mate, the application still had not been updated.

Ryan stopped tweeting on his personal Twitter account on August 5, six days before the official announcement from the Romney campaign. The organization that ran Romney's operation was Targeted Victory, with significant overlap with Ryan's social media apparatus early after the announcement. However, in principle, and

as is generally the case, lawmakers are careful not to use their official Twitter and Facebook accounts to campaign on a presidential ticket. According to Fox News, Ryan's Twitter followers almost immediately rose by 170,000 after the announcement by Romney. Conversation about Ryan peaked at 3,749 tweets per minute. Before the announcement, he had an average of 675. The event accounted for five out of 10 of Twitter's top trending topics in the United States. During the 16-minute announcement speech by Romney, Ryan's Facebook page added 6,000 followers.

A new Romney-Ryan Twitter account was revealed almost as soon as the announcement had been made. Ryan's vice presidential nominee handle, @PaulRyanVP, was unleashed by campaign officials. It gained 60,000 followers in less than eight hours. Ryan's campaign tweeting was done on the new handle. Similarly, on Facebook the PaulRyanVP page received the action. The Romney team also rolled out the page the morning of the announcement. Ryan's personal Twitter account gained more than 44,000 followers in its first three hours. His original Facebook page was adding more than 300 new fans a minute by noon on that day. Just over two days later, it had more than 100,000 followers. Ryan's original Twitter account gained over 10,000 followers in that time.

In comparison to other prominent lawmakers in the House of Representatives, he soon developed more followers on Twitter than Republican House leader Eric Cantor, and was rivaled only by House Speaker John Boehner and former House Speaker Nancy Pelosi.

A Romney-Ryan smartphone application was made available for both iPhone and Android users. Supporters were able to download the Romney-Ryan campaign application throughout the course of the presidential election period, with between 50,000 and 100,000 installs accounted for by the Android version of the application alone. It was designed by the Romney-Ryan social media team to make it easy for smartphone users to become involved with the campaign. The Romney-Ryan application allowed users to learn about the campaign, receive the latest news and updates, donate, and share campaign information with friends and family. It featured a biography part, which allowed users to learn about Mitt Romney and Paul Ryan. The news part of

the application allowed its users to stay up-to-date with the latest campaign blogs, videos, and breaking stories available on social media. The events feature allowed users to explore and find campaign events near them.

On the evening of October 11, 2012, at Centre College in Danville, Kentucky, Ryan debated incumbent Vice President Joe Biden in the only vice presidential debate of the 2012 election. The collective press announced that Ryan was the winner on social media. Voters' opinions of the debate were tweeted instantaneously that evening, as well as broadcasted in Facebook, LinkedIn, and Myspace status updates. The event was also broadcasted on social media, with the YouTube Political Channel allowing viewers to watch the debate live on its stream of the event.

During the event, some have claimed that Vice President Biden played the aggressor and repeatedly refused to allow Ryan to talk. An analysis of the evening's event could adequately be characterized as contrasting styles from the two politicians involved. Ryan supporters and some others have argued that Ryan mainly focused on substance, and Biden for the most part presented talk of innuendo. These contrasting styles over the course of the debate were shown by Ryan's retort to a Biden accusation about Romney's campaign's theme of "we are the 47 percent," with the response that, "sometimes the words don't come out of your mouth the right way."

A CNN survey of registered voters who watched the vice presidential debate found Paul Ryan the winner 48 to 44 percent. The registered voters interviewed also voted that Ryan communicated more clearly, by a margin of 50 to 41 percent. Additionally, Ryan was voted more likeable by a margin of 53 to 43 percent.

That month Ryan was given the cover story of conservative magazine *Townhall*, with prominent coverage on its Web site Townhall.com. The Web site continues to keep a Paul Ryan news page as one of its trending topics, with videos of his election and postelection speeches embedded in the page, in addition to a Twitter feed about him.

Days after the 2012 election, Ryan's personal Facebook page had 312,000 "likes." Over

323,000 were following him on his personal Twitter account. He had compiled a record of 1,177 Tweets on the account by that time.

Ryan's social media presence was not significant enough to bring victory to Romney's campaign. The 2012 presidential election was one of the few times in history that the candidates did not both win their home states. The loss of Wisconsin proved detrimental to the Romney campaign. And Ryan did not manage to convince all counties in his district to vote for Romney. Obama won Kenosha County, Racine County, and Milwaukee County. Romney took Walworth County, Rook County, and Waukesha County.

Throughout the 2012 presidential election, social media characterized Romney and Ryan as having two different budget plans. Some speculated that if the Romney campaign were victorious, the vice president of the United States would be more of an expert on the federal budget than the White House budget director. After the election, and with Ryan's elevated profile, there was speculation that if the GOP retains the House in the future, he may step up to majority leader, or perhaps speaker.

S

Sanders, Bernie

Bernard Sanders (1941–), more commonly known as Bernie Sanders, is currently the junior U.S. senator from Vermont. He was elected to the U.S. Senate in 2006 as an Independent. Sanders previously served as the U.S. Representative from Vermont's at-large district from 1990 to 2006, and as Mayor of Burlington from 1981 to 1989.

The son of Polish immigrants, Sanders was raised in Brooklyn, New York. He first attended Brooklyn College, but later transferred to the University of Chicago, where he earned a B.A. in political science in 1964. At the University of Chicago, Sanders became a critic of economic liberalism and a proponent of social democracy. He subsequently spent time on a kibbutz in Israel, which solidified his worldview and lifelong identity as a democratic socialist. Although he has proudly called himself a socialist ever since, Sanders distinguishes his understanding of socialism from communism proper. At its heart, Sanders's political platform is devoted to working and middle-class families, children, the elderly, and the poor. As a result, he has been a proponent of universal health care, public education, environmental protection, immigration reform, and withdrawing American troops from Iraq.

Sanders was the third socialist to be elected to the House of Representatives, and the first

ever to be elected to the Senate. He was the only Independent during his time in the House, and is today one of two Independent members of the Senate. As a longstanding critic of both Republicans and Democrats, Sanders has known few political allies in the course of his career. Even the more progressive members of the Democratic Party, who would otherwise make natural allies, have been critical of his abrasive speaking style and unwillingness to compromise on almost every political issue. However, Sanders has happily embraced his marginal status, which enables him to speak freely and directly both in Congress and to the media.

This status sets him apart from his colleagues in both parties, who are more often than not limited by their respective platforms in what they can publicly say. Sanders's blunt and charismatic style not only endears him to his constituents, but also makes him a natural social media phenomenon. He is known for clear, powerful, and memorable lines that can be easily disseminated and shared on Facebook and Twitter. Although he lacks political alliances in the American legislature, he nonetheless commands a vast social-media following that most Republican and Democratic politicians would envy.

The Sanders administration officially makes use of Facebook, Twitter, YouTube, and Google+. These tools enable to him to share news and

updates, educate his followers about the strengths and drawbacks of proposed bills in the House and the Senate, and to bolster his political campaigns. They also enable him to share pictures and video clips, announcements for upcoming media appearances, as well as words of thanks to his supporters. Although Sanders maintains a staff to manage his social media presence, he often posts comments, adding a personal touch to an otherwise formal affair, further endearing him to his already loyal followers.

Facebook

Like most politicians, Sanders's primary social media platform is Facebook. To date, his official Facebook page has over 162,000 fans. Visitors are greeted by a photo of Sanders, along with a seasonal background image of Vermont, the latter routinely updated to reflect the time of year. The "About" page provides Sanders's biographical data, educational background, employment history, contact information, and select political achievements.

The main page features an extensive history of posts, which are made almost daily. Typically, these posts include a summary or excerpt of an official press statement by Sanders regarding a current political issue, followed by a link to the official Web site of the Sanders administration providing further information. Sanders's Facebook posts also commonly include images featuring a photo of Sanders alongside a catchy quote. Other posts feature videos of Sanders's media appearances on television, often from the progressive cable news channel MSNBC. Regardless of the type, all posts are designed to be shared and distributed by Facebook users. The conciseness, pithiness, and rhetorical power of these posts make them easy to consume on Facebook's unique user interface.

For example, in November 2012, during the negotiations between Democrats and Republicans in the U.S. Congress concerning deficit reduction in the federal budget, Sanders posted the following quote:

Just think of the arrogance of these CEOs who were bailed out by the American people when their greed and recklessness nearly destroyed the international financial system, and now

they come to Congress to lecture the public about the need to cut programs for working families who are struggling from the recession that they caused.

This quote was juxtaposed alongside a photo of Sanders looking intensely at his audience and speaking passionately with an index finger pointing in the air. The remarkably forthright nature of the quote, which is highly unusual for a Washington politician, along with the charismatic image of Sanders delivering his signature fiery oratory, is a common feature of Sanders's Facebook activity. It is also the reason that his followers hold him in such high esteem.

The sharing tool allows those who are not official fans of Sanders's Facebook page to receive posts in their news feed, and should they choose, to share those posts in turn. This enables Sanders to widely disseminate his talking points and to gain new followers in the process. The provocative nature of his Facebook posts are also known to generate lengthy, if somewhat disordered, discussions. These discussions follow below each post, and below each sharing of each post. Facebook users are thereby able to express their opinions about a particular issue on both Sanders's page, as well as on their personal pages. These opinions often take the form of routine praise for Sanders's viewpoints and criticism for those he opposes. It also takes the form of reasoned exchange. It is not uncommon for a typical post on Sanders's Facebook page to receive thousands of "likes," to be shared thousands of times, and to generate thousands of comments. These comments can themselves receive "likes," and enable followers to network with each other, further strengthening Sanders's support base.

Twitter

Sanders's second-largest social media following can be found on Twitter, where he draws over 127,000 followers. His Twitter account, @Sen-Sanders, features the same background image as that found on his Facebook page, along with an official photo of Sanders against a second, smaller background image. To date, Sanders and his staff have made over 5,000 tweets. Although the overwhelming majority of tweets are made by his staff, many are made by Sanders, and end with a

simple “-B”. Sanders also follows over 900 other accounts, keeping him and his staff up-to-date with key players on Twitter.

Following standard Twitter syntax by politicians, Sanders offers his followers daily news updates and announcements in brief form. When appearing on television, Sanders uses the “@” symbol to acknowledge his host (e.g., @Wolf-Blitzer), which attracts the attention of those who happen to follow or search for that host’s Twitter account. Typical tweets are followed by links in the form of shortened URLs that fit within Twitter’s 140-character limit. They are also followed by hashtags (e.g., #Budget and #FiscalCliff) designed to promote or “trend” those tweets. Often, these hashtags will be included in a sentence, which economizes on space. Even within Twitter’s extreme character limit, Sanders and his team manage to convey the same sense of passion, outrage, and wit characteristic of his Facebook posts. An example of such a tweet is the following from late November 2012:

Lloyd Blankfein, CEO of @GoldmanSachs, is paid more in two hours than the average #SocialSecurity recipient earns in a year.

Just as Facebook’s user interface permits unique forms of communication and expansion of user support, Twitter has enabled Sanders to increase his following because of the rapid-fire nature of tweets. The most famous example of this phenomenon occurred in late 2010, when Sanders strongly objected to the Tax Relief, Unemployment Insurance Reauthorization, and Job Creation Act of 2010, which extended the so-called Bush tax cuts to preserve historic low rates for the wealthiest Americans. Sanders argued that extending these tax cuts would place even greater burdens on social programs and result in further harm to working- and middle-class families, the poor, the elderly, and children. He took to the Senate floor and spoke for no less than eight and a half hours, attacking the compromise in his characteristic style. As news of the speech spread, large numbers of “tweeters” began following, discussing, and supporting his effort. The discussion famously generated a unique hashtag, #FiliBernie, although the speech was not technically a filibuster. Virtually overnight, Sanders

gained 4,000 Twitter followers. The story was listed by social media news Web site Mashable.com as one of the top Twitter trends of December, even outranking those by pop music giants Taylor Swift and Miley Cyrus.

YouTube

Compared to Facebook and Twitter, Sanders has few followers on YouTube. To date, he has managed to accumulate nearly 8,000 subscribers. However, this comparatively low number of subscribers is not a reflection of the efficacy of Sanders’s YouTube content, but rather of the nature of YouTube. Unlike Facebook and Twitter, it is simply less common for users to become subscribers to an official YouTube channel. Despite the low number of subscribers, Sanders’s YouTube videos have managed to receive well over 2 million views.

Because YouTube’s user interface is not amenable to the kind of colorful background images characteristic of Facebook or Twitter, Sanders’s YouTube channel is fairly modest in appearance. However, what it lacks in colorful appearance it more than compensates with lively visual content, for it is through YouTube that Sanders often provides video clips and links to such clips on Twitter.

Google+

Despite being one of the more recent social media platforms, Google+ has proven surprisingly popular with Sanders’s followers. To date, over one million users have added Sanders to their “circles,” demonstrating the unique power of Google+ to reach new public audiences.

Sanders uses the same official photo, along with the same background image, as those found on Facebook. The updates and announcements are also very similar in style and format, and in fact share much of the same content. User participation also mirrors Facebook, with followers making comments, endorsing each other’s comments with a “+1,” and sharing Sanders’s posts on their accounts.

Sanders was one of the first American politicians to start a Google+ account. While Google+ is very similar to Facebook in its user interface, it offers different tools that the Sanders team has utilized to communicate with supporters. For example, in

November 2011, just two months after Google+ was made available to the public without the need for an invitation, the Sanders team polled its followers on whether they supported or opposed a constitutional amendment to reverse the U.S. Supreme Court decision on *Citizens United v. Federal Election Commission*, which permitted unrestricted expenditures by independent entities (e.g., corporations and unions) in politics. Despite being an early and not altogether reliable use of the polling tool, Sanders nonetheless established himself as a pioneer on Google+, once again earning the recognition of Mashable.com.

Senator Bernie Sanders in Kabul, Afghanistan, on February 20, 2011, as part of a congressional delegation visiting the Afghan National Police Academy. Sanders is active on social media, and in March 2012, he won the social media equivalent of an Academy Award for the Best Member of Congress on Social Media.

Recognition

Sanders has received widespread recognition for his social media efforts. In late 2011, Mashable.com nominated Sanders for the category of “Must-Follow Politician on Social Media,” along with Barack Obama, Cory Booker, and Ron Paul. In March 2012, Sanders won a prestigious Shorty Award, the social media equivalent of an Academy Award, for the category of Best Member of Congress on Social Media for his use of Facebook, Twitter, and Google+. The award was presented by *The Daily Show* correspondents Samantha Bee and Jason Jones. Sanders took the occasion to acknowledge the power and importance of social media to directly connect with the public, and to have a debate about issues that are rarely discussed in mainstream media. He highlighted in particular the possibility of having meaningful conversations on social media about the disappearance of the middle class, increasing inequality in income and wealth, rising levels of poverty, and the need for better healthcare. Sanders’s belief in the democratic power of social media is in part a reflection of his disenchantment with traditional corporate media.

In March 2012, Edelman Digital, a division of the public relations giant Edelman, issued a report concerning the most influential U.S. politicians on Twitter. Partnering with Simply Measured, a prominent social media analytics tool, Edelman measured Twitter “success” through a newly devised set of metrics, which included engagement, Twitter mentions, amplification, growth in the number of followers, and “tweetlevel” influence, or the number of times a politician’s tweets have been retweeted. Studying a time period ranging from September to December 2011, the study observed 456 Twitter accounts and nearly 60,000 tweets. Edelman revealed that Sanders ranked first in influence, first in engagement, third in trust, and fourth in popularity. Sanders’s success came as a surprise to commentators, as Republicans far outnumbered Democrats both in terms of Twitter accounts and efficacy of tweets.

Saturday Night Live

Saturday Night Live (SNL), a comedy variety program broadcast live on NBC has been an essential contributor to America's political culture since its debut in 1975. Through its parody news segment, "Weekend Update," and its extended comedic sketches in which cast members play presidents, candidates, and other members of world politics, SNL has been and continues to be at the forefront of mainstream political critique. The show's prominence in social media peaked during the 2008 election season, a result of the confluence of a cast member's uncanny portrayal of the Republican vice-presidential nominee, the ascendance of YouTube and other video-sharing Web sites, and the launch of the TV archive site Hulu.com.

SNL and Politics: A Brief History

Saturday Night Live first aired on October 11, 1975. Developed by Lorne Michaels, who still serves as the show's executive producer, SNL was intended to attract a new generation of TV

watchers: members of a young (18–34), disillusioned, cynical generation reeling from the Watergate scandal and the resignation of President Richard Nixon, and facing the prospect of an election cycle featuring an incumbent who had neither been elected president nor vice president. SNL offered an unpredictable and irreverent mix of sketch comedy, popular music, spoofs of TV shows and movies, and most prominently, political satire. From its first episode, the presidency was the main target of its satirical barbs, with cast member Chevy Chase portraying a version of then-President Gerald Ford as a bumbling fool. While the show has undergone many changes of cast and format in its 38 years on the air, its most constant and most remarked upon feature has been its comedic skewering of politics and politicians.

Political satire and jokes about (and at the expense of) politicians have always been staples of SNL. On SNL, such comedy takes two forms: its regular "Weekend Update" segment featuring mock news reports about politics, and longer sketches in which cast members portray politicians (especially presidents and presidential candidates). Along with Chevy Chase's groundbreaking spoof of Gerald Ford, memorable SNL portrayals of politicians include Dan Aykroyd's takes on Richard Nixon and Jimmy Carter; Dana Carvey as George H. W. Bush and Ross Perot; Darrell Hammond as Bill Clinton and Al Gore; and Tina Fey as Sarah Palin.

Additionally, politicians regularly make appearances on the show, particularly during election years. President Gerald Ford was not only the first target of SNL's political spoofs, but, also the first president to make a cameo appearance. Other politicians playing themselves on SNL have included both Bush presidents, Vice President Al Gore, Senator Daniel Moynihan, New York Mayor Rudy Giuliani, and presidential candidates Ross Perot, Ralph Nader, John McCain, Hillary Clinton, and John McCain.

SNL, Sarah Palin, and Tina Fey

In terms of use of and impact upon social media—and possibly, impact upon voters—nothing to date has compared to the 2008 series of portrayals of Sarah Palin by Tina Fey. The 2008 season premiere featured a skit starring Fey, a former SNL

cast member and head writer, as the newly nominated Republican vice-presidential candidate, Alaska governor Sarah Palin, and Amy Poehler as Hillary Clinton. While Poehler's portrayal captured little of Clinton's essence, Fey's visual and vocal resemblance to the real Palin were uncanny. The episode received the highest Nielsen ratings for a premiere since 2002, and attracted so much media attention that over 14 million people watched the sketch on NBC.com and Hulu.com, making it the most-viewed clip ever on the network's Web site, as well as the most-watched viral video overall to that point.

The unprecedented reach and popularity of the initial Fey/Palin sketch led to five subsequent Palin portrayals by Fey, each attracting large broadcast and online audiences. In one sketch, the real Sarah Palin appeared side-by-side with her impersonator; in another, Fey and Poehler parodied a Palin interview that had been conducted by *CBS Evening News* anchor Katie Couric. While the original CBS news broadcast reached 6.2 million viewers, the SNL skit was watched by 7.9 million viewers on television and 11.1 million viewers on Hulu.com and NBC.com. The impact of SNL's Fey/Palin sketches was also felt by Hulu, a video archive site launched by NBC Universal and News Corp. in March 2008. By November of that year, Hulu had become a top-10 Web site, thanks in large part to viewers of Fey's Palin impersonations.

SNL's Effects on Politics: An Ongoing Debate

The centrality of political satire has been a constant throughout SNL's 38 years on the air. Whether SNL's treatments of politics and politicians have had any measurable effects, however, has been debated. There appears to be agreement that SNL, like other political comedy shows, raises viewers' awareness of politicians and political issues and may contribute to the formation or reinforcement of political views and attitudes; may affect how political campaigns are run; and may have some influence on how political reporters cover elections. Less clear is whether SNL affects voting behavior or results. Several studies conducted during and after the 2008 campaign found evidence for a variety of so-called Fey effects: scholars and

political journalists found that Tina Fey's name popped up unbidden during voter interviews about the election; voters exhibited increasingly negative attitudes toward Palin; Fey's impressions caused viewers to pay more attention to the traits of the real Palin; and SNL contributed to a broader journalistic narrative that Fey was hurting the GOP's electoral prospects. However, even those reporting on these various Fey effects acknowledged that the comedian most likely did not affect the election's outcome.

Moreover, as several critics have noted, the satiric focus of the cast members' portrayals of politicians is on their physical traits, both visual and verbal, not on their actual politics or policies. (Tina Fey appears to be the exception to this rule: Fey's impression brilliantly captured Palin's look, voice, and mannerisms while also commenting on her qualifications for the vice presidency.) Indeed, the fact that so many of the targets of SNL's jabs willingly make appearances on the show suggests that they cannot have been too badly skewered by the program.

Conclusion

While critics agree that SNL has permanently changed the face, nature, and scope of American political humor and political coverage by "real" news sources, at the same time, they acknowledge that SNL's barbs are much less sharp than those offered by Comedy Central's *The Daily Show With Jon Stewart* and *The Colbert Report*. This may not be surprising given that SNL, as a broadcast offering, must entertain a mass network audience and is therefore less free to offer the more pointed and probing critique of politics that fans of Jon Stewart and Stephen Colbert have come to expect. Still, the political skits and the largely politics-focused "Weekend Update" segment remain the most popular, prominent, and digitally shared elements of *Saturday Night Live* and it appears they will remain so for the foreseeable future.

Schools4All

Schools4All is an education fundraising project by Pencils of Promise, with the highly visible support of Canadian pop idol Justin Bieber. The project's Web site uses a custom platform provided by StayClassy.org that allows users to create personal fundraising pages, with funds going to efforts to build schools in developing nations.

Users are given the ability to customize these pages, add multimedia files, share via social networks, and create widgets. The user who raises the most money receives a school visit by Bieber as an incentive. Fundraising pages are open to all U.S. residents over 12, so technically the prize is the ability to choose which school Bieber visits. The expectation is that the user base will skew young, and that the winner will choose his or her own school. In its first months, Schools4All raised enough money to build seven new schools. Upcoming schools identified in 2012 included Xepocxuc Preschool and Primary School in Guatemala, Houay Yen Preschool and Primary School in Laos, and Lizarco Preschool in Nicaragua.

Pencils of Promise was founded in 2008 to raise money to build schools in developing countries. Pencils of Promise has funded the construction of more than 50 schools in Ghana, Guatemala, Laos, and Nicaragua, as well as distributing school supplies in more than 50 countries. As of the end of 2012, 32 schools were under construction, and 76 had been completed, in addition to the upcoming schools being funded. The charity was inspired by founder Adam Braun's experiences backpacking through developing nations as a college student, and his perception of a need for an international nonprofit group that partnered with local staff and participating villages to enact educational change. Internationally recognized and receiving praise from Barbara Walters and Desmond Tutu, Pencils of Promise has distinguished itself as a leader in social media engagement, having been founded by a member of the millennial social media generation. A Brown University alumnus, Braun was listed on *Wired Magazine's* 2012 "Smart List of 50 People Changing the World," and he was honored by the United Nations and the Clinton Global Initiative.

Pencils of Promise discloses its financials on its Web page, specifically drawing attention to them and making them easy to find. Doing so underscores the fact that a full 84 percent of its 2011 expenses were spent on program services—an admirable portion, larger than that of many charities tracked by watchdogs like Charity Navigator. Only 9 percent of the charity's expenses were spent on fundraising; the use of social media, in particular, can help keep fundraising expenses low without lowering the profile of the charity's

brand, and initiatives like School4All generate free publicity thanks in no small part to the popularity of Bieber. The financial highlights section also draws attention to the fact that 75 percent of donations are under \$100, emphasizing the role of grassroots fundraising over corporate sponsorship and patronage. Corporate partners include Post Foods, Pizza Hut, JPMorgan Chase, Google, Dolce and Gabbana, 1-800 Flowers, Activision, Pearson Education, Pop Chips, Viacom (the parent company of MTV), and Faber-Castell.

The Schools4All contest has been run twice. In its first year, the winning fundraising page, raising \$51,738.50, was that of the Fiocchiario family. Over 20,000 different fundraising pages were created, each representing at least one participant (with many more donors). The contest's first year raised \$305,975, enough to fund 15 new schools. After the initial fundraising year ended in June 2011, Schools4All changed the terms of the prize. Instead of the prize automatically going to the user raising the most money, virtual raffle tickets were generated. Each \$25 raised generated one ticket. (The choice of \$25 likely is not random; it is the amount that Pencils of Promise first started with.) The winner of the Bieber visit was selected randomly from these virtual tickets. On top of that, the top three fundraising schools would receive plane tickets (10 to the first-place school, five to the second, two to the third, as well as a chaperone plane ticket for each) for fundraising students to visit the school Bieber would be visiting. The change created an incentive for fundraisers to raise as much money as possible, without disincentivizing fundraisers nowhere near the leader as the end of the contest period drew close. Other prizes provided by corporate sponsors included gift certificates for shopping sprees and Nook e-readers.

Schumer, Charles

Charles Schumer is the current and most senior senator from New York. Currently, he is the third-highest-ranking Democrat in the U.S. Senate. The gregarious Schumer is known for his love of the spotlight (Washington insiders joke that the most dangerous place to be is between Schumer and a camera) and his outspoken and articulate defense of liberal issues. He is known as a policy wonk and brilliant strategist who has been given credit for the Democrats retaking control of Congress in 2006. Many Washington insiders believe that he will one day be the leader of the Democrats in the Senate.

Schumer was born in Brooklyn, New York, to Jewish parents. From the beginning, Schumer was an ambitious overachiever. He graduated as valedictorian of his high school class, and had a perfect score on the Scholastic Aptitude Test (SAT). Schumer graduated from Harvard and Harvard Law School. At the age of 25, in 1974, he was elected to the New York State Legislature, becoming the youngest member since Theodore Roosevelt. He served in the New York State Legislature until 1981.

In 1980, Schumer was elected to the U.S. House of Representatives when Elizabeth Holtzman retired. Schumer served in the House of Representatives from 1981 to 1999. While serving as a congressman, Schumer compiled a liberal voting record. He voted in favor of gun control and consumer protection laws. Schumer voted for the Brady Bill in 1990, which established a seven-day waiting period in order to buy handguns. He also was one of the sponsors of the Assault Weapons Ban in 1994.

In 1998, Schumer was elected to the U.S. Senate. Supporters note that he quickly became a rising star in the Senate known for his skillful use of

media (he is still a frequent guest on the Sunday morning news shows) while also citing his knowledge of issues and skills as a political strategist. After the 9/11 terrorist attacks, Schumer successfully fought for aid to New York City. Schumer was easily re-elected to the Senate in 2004 and 2010. Like his Republican colleague Charles Grassley (who frequently visited all of Iowa's 99 counties), Schumer boasted about visiting all of New York's 62 counties.

In the Senate, Schumer serves on a variety of committees, including the Finance, Judiciary, and the Rules Committee (he became chairman in 2006). Schumer quickly moved up the ranks of the Democratic Party in the Senate. In 2004, he became the chairman of the Democratic Senatorial Campaign Committee (DSCC), a position he held until 2008. As leader of the DSCC, Schumer recruited candidates to run for the Senate. Although an outspoken liberal with an extensive

liberal voting record, Schumer proved to be a pragmatist as DSCC chairman. He recruited candidates who could compete in Republican states. For example, Schumer recruited Jon Testor to run for the Senate in Montana. Testor opposed gun control and gay marriage. He proved to be a much better fit for Montana than previous Democratic candidates, and was elected to the Senate in 2006. In 2006, Democrats regained control of Congress for the first time since 1994. Schumer's decision to recruit moderate to conservative Democrats to run in Republican states was cited as one of the reasons Democrats regained control of Congress.

In addition, Schumer became vice chair of the Democratic Conference in 2006. He is currently the number-three-ranking Democrat in the Senate. Many political experts believe that he may one day become the leader of the Senate Democrats if Senate Majority Leader Harry Reid either retires or is defeated in his re-election bid.

Secretary of Defense Leon E. Panetta shares a word with Senator Charles E. Schumer (left) before boarding his plane at Niagara Falls Air Reserve Station, August 9, 2012. In March 2012, Schumer and Senator Richard Blumenthal urged the Equal Employment Opportunity Commission and the Department of Justice to investigate whether employer demands for private information like Facebook and e-mail passwords as a precondition for job interviews was a violation of federal law.

During the George W. Bush administration, Schumer was accused by conservative critics of filibustering and blocking Bush's efforts. Critics noted that he regularly filibustered many of Bush's judicial nominees. On the other hand, Schumer voted for Michael Mukasey, Bush's nominee for attorney general in 2007. During the last four years, he enthusiastically supported the policies of President Barack Obama. He voted for the stimulus plan, the Affordable Care Act, and the Dodd-Frank Act. Schumer played an active role in negotiations over the fiscal cliff. He urged Democrats and President Barack Obama to stand firm on renewing tax cuts for the middle class and on raising taxes on the wealthy. Schumer also actively campaigned for aid for the victims of Hurricane Sandy, which included his constituents in New York City.

Critics have claimed over the years that Schumer is too cozy with Wall Street and financial firms, contradicting his image as a liberal reformer. Schumer was also criticized a few years ago for refusing to turn off his cell phone on a flight when requested by a stewardess. Nonetheless, Schumer has been free of any scandal or allegations of wrongdoing. Charles Schumer has proven to be a major player in the Senate, despite his love of the spotlight and his outspoken liberal record, which, it has been noted, can often overshadow his sophisticated grasp of public policy issues and his skills as a master political strategist.

Search and Scrape Capability

On January 19, 2012, the Federal Bureau of Investigation (FBI) posted a request for information asking software vendors for an application that can "search and scrape" social media Web sites for information about potential global and domestic threats. The desired software would need to be able to search social media Web sites like Facebook, Myspace, Twitter, YouTube, and Flickr, "scrape" the relevant information from those Web sites, and analyze the findings. While the request for information states that the search and scrape software would only access messages that the user has made publicly available, the request raises important civil liberties questions.

The FBI notes a number of important requirements in the search and scrape software it is requesting. First, its search and scrape capabilities must be automated, and users need to have the freedom to create and define keyword parameters. Second, the software must be able to filter data based on the search criteria. Third, the software must be capable of providing instant alerts about

breaking events and emerging threats, and display those events on geospatial maps. These maps need to be able to incorporate U.S. domestic terror data, worldwide terror data, U.S. embassies, consulates, and military installations throughout the world, weather conditions, and traffic video. Finally, the software needs to be able to search and monitor all publicly available postings from social networking Web sites, as well as translate postings in foreign languages into English.

Along with the specifications for the software's technological capabilities, the request outlines the purposes of the software. On one hand, the search and scrape program will assist the FBI in intelligence-gathering operations. The monitoring of social media will assist law enforcement in identifying potential threats and developing threat profiles. Based on the data gathered, the software will assist in helping to frame appropriate responses to potential threats and developing effective countermeasures. The FBI believes that the monitoring of social media sites represents a critical component in national law enforcement and security policy.

The search and scrape software will also assist in other important governmental functions. The software will allow the FBI to respond more effectively to crises because social media often reports problems faster than formal channels of emergency communications. Search and scrape will also assist law enforcement in planned operations and special events where gauging security risks and the required security responses is often quite difficult.

In total, the search and scrape application requested by the FBI would enable the organization to accomplish a host of important tasks. From counter intelligence, surveillance, and reconnaissance to terrorism and cybercrime, fast and efficient monitoring of social networks represents a necessary step in the evolution of law enforcement's efforts to stay informed about changing events and potential threats to public order and safety. Moreover, the FBI insists that the software will not have access to private information that a social network user has not made public. Its search and reporting features will be limited only to information that is publicly accessible and placed in the public domain voluntarily by the user.

Concerns

Despite the FBI's assurances that the data mining performed by the search and scrape software will be limited to public information, the software request raises a number of important civil liberties concerns, and has drawn the attention of civil rights groups. These groups raise a number of important objections to the proposed software requested by the FBI. First, the Supreme Court has consistently ruled that government may not engage in acts of "prior restraint" when it comes to freedom of speech. This means that the government may not preemptively rule speech by individuals as impermissible, except in very narrowly defined situations (such as yelling "fire" in a crowded theater). While the search and scrape software certainly does not constitute prior restraint on the part of the government, critics worry that the knowledge that the government is monitoring what is posted on social media Web sites will have a chilling effect on free speech. The constant monitoring means that everything an individual posts will be reviewed by a government computer, and this may lead to a general reluctance to post anything publicly that could attract unwanted attention.

Second, the collection and warehousing of information scraped from social media sites is troubling to many people. It may be one thing for government to watch what is being said, but it is quite another for the government to maintain databases of postings by individuals. For some critics, this is tantamount to the government keeping secret files on citizens, a behavior these critics see as incompatible with living in a free society. In addition, the software's constant monitoring creates a kind of surveillance culture on the Internet, where every citizen is treated as a potential criminal. This condition is seen as inimical to a legal culture that presumes the innocence, rather than the guilt, of citizens.

Finally, critics observe that the very nature of social networking makes even a targeted search and scrape system impossible. If the government were to limit the use of the program to target individuals already suspected of criminal or potential criminal activity, the problem is that such a person is connected to dozens if not hundreds of other people through social networking. Separating suspect individuals from the people they are

networked with is impossible, which means that everyone falls under the government monitoring.

Conclusion

Clearly, search and scrape programs offer tremendous advantages to law enforcement by improving the capacity of law enforcement agencies to maintain situational awareness and monitor and prevent illegal behavior. There is also no question that law enforcement must be able to adapt to the changing conditions of technological communications. At the same time, search and scrape programs in the hands of the government raise important civil rights concerns that must be adequately addressed. Balancing civil rights with the need for greater security in the digital age continues to be one of the great challenges of the 21st century.

Search and Seizure Law and Policy

Generally, police do not need a warrant to search in a public forum such as the street or a park. Anything that is in plain sight, plain smell, or plain hearing can be used by police officers to gain probable cause for an arrest. So, if a person

is soliciting prostitutes on the street (plain sight), smoking marijuana in a park (plain smell), or discussing the exploits of a crime in a city square (plain hearing), then the officer can act. This seems like common knowledge, but what most people do not realize (or refuse to believe) is that social media sites are also public forums. They are online (which is open to public), and a person is invited to join the community (and will sign terms of agreement). Even though people may access these sites from their smartphones or a laptop in their privately owned home, once an individual is online, he or she is in public. Thus, what a person says, writes, or posts is open to the public, including the police. Going online is akin to going into the middle of a park or a crowded restaurant and screaming at the top of one's lungs.

Government agencies are taking advantage of people's ease with social media. As many as 80 percent of police agencies are now using social media as a tool for criminal investigation, and the number continues to rise. For example, the New York Police Department (NYPD) uses facial recognition technology to scan Facebook pages to look for wanted criminals or those with outstanding warrants. The NYPD has an entire unit dedicated to mining Facebook, Twitter, and other social media sites. Most federal investigatory agencies also have members who mine social media sites for evidence of criminal activity. For example, the Department of Homeland Security (DHS) has a private Twitter account, and uses TweetDeck to scan millions of tweets for suspected terrorist activity (although the DHS claims that it does not follow specific individuals).

Any information left public on social media is open to investigation by police. Information that directly implicates a person can be used to arrest the person. Furthermore, social media sites such as Foursquare can be used to locate individuals. There are many examples of police agencies making arrests based upon information found on social media sites. A Kentucky man was jailed for posting a photo of himself siphoning gas. A Washington, D.C., man was arrested after he used a laptop that he stole to post a picture on the victim's Facebook page. The picture showed him wearing a fur coat that he had also stolen from the victim. In California, authorities brought down an Al Qaeda terrorist cell by using an undercover agent to create

a virtual relationship with the defendants through Facebook and Skype. In another case, a defendant was convicted of murder based on evidence found on Myspace. Police also create fake accounts to access a suspect's page through the assistance of a cooperating witness who is a Facebook friend with the suspect. Furthermore, many people will accept friend requests from people they do not know in order to increase their number of friends, thus making the police's job very easy.

Criminal Investigations, Social Media, and Privacy

Social media sites are updated daily with billions of pieces of data, including pictures, videos, locations, addresses, and unwitting confessions. It is a valuable source for investigative agencies, one that requires little work or effort. This is an innovative way for police agencies to do their jobs, but it raises some privacy concerns. The Fourth Amendment of the U.S. Constitution protects "against unreasonable searches and seizures." People have the highest level of protection in their homes and on their persons. Therefore, in order to search a person or the home, police must obtain a valid warrant from a magistrate, or have articulable probable cause (the same level needed to obtain a warrant).

The Fourth Amendment also protects people from warrantless searches obtained with new technology, such as GPS tracking and infrared cameras, even if the police are in a public forum. For example, a police officer could not use an infrared camera from the street to peek into a home, unless the officer had a valid warrant. Any evidence obtained from a warrantless search or one proceeded upon without probable cause will not be admissible in court. However, this only applies to evidence gained in areas where citizens have a reasonable expectation of privacy. Thus, information made available in a public forum will most likely not have protection. Since Facebook and Twitter are public forums, there is almost no reasonable expectation of privacy, thus police can search and seize information without a warrant or probable cause.

The government can gain access to social media information through several traditional court orders, such as warrants and subpoenas. In some instances, the government can compel disclosure without a warrant (which requires

British officers from the West Midlands police department seize a laptop during a national child abuse operation targeting known and suspected child sex offenders in June 2012. Three people were arrested as a result of the search. In the United States, a warrant is needed to seize a document on a computer.

probable cause). The Electronic Communication Privacy Act (ECPA), which governs the protection of online information, was passed in 1986. At that time, Congress only foresaw cell phone and e-mail communication. Thus, the ECPA was created under the belief that people would download e-mails, open and read them, and then delete them. Congress did not foresee a permanent record of social media sites.

As a result, under the current law, if information has been posted for less than 180 days, the government needs a warrant to gain access. If the information has been posted for more than 180 days, then it is assumed to be abandoned (like a letter thrown in the trash). Thus, the government can compel the service provider to disclose the information with a warrant, or an administrative subpoena, or a court order (which does not require probable cause).

The law has created a confusing contradiction. A document on a computer can only be obtained through a warrant, but if it is stored in the cloud or through an e-mail service provider, then the government is only required to obtain (a less strict) subpoena in order to access it. Moreover, the ECPA does not speak to location tracking,

thus no court order is needed for police to use social media or cell phone information to track individuals.

Defendants do not have the same legal abilities to access social media information in mounting their defense, as the rules of evidence require them to obtain a subpoena to access social media sites. Furthermore, any subpoena obtained can be challenged by the user or the social media site (this would not include information that is publically available). Finally, even if the evidence is obtained, this does not mean that it will be admissible in court because it may be dismissed for several reasons, including hearsay, inability to authenticate, and prejudicial history.

Social Media Sites: Pushing Back

After several years of customer complaints, social networking sites have begun to allow consumers to make information private, but only 25 percent of users take the additional step of making their pages private. The question is whether the ability to make that information private now creates a reasonable expectation of privacy; however, private information may not be as private as one thinks. For example, Facebook will often let information that one sets as private to be posted on a friend's page, which may not be private. Furthermore, lists of friends allow police officers to track known accomplices or other persons of interest who may have information that can lead to an arrest.

Additionally, the U.S. government frequently contacts social media sites for assistance in criminal investigations, and the sites often comply. At the end of 2012, Google reported receiving approximately 8,400 requests for information from government agencies in the United States over the last five years. Of that total, approximately 5,800 were based on subpoenas, 1,900 were based on warrants, and the rest were other types of requests under the ECPA. Google reported that it complied with approximately 90 percent of all government requests. Twitter also reported approximately 700 such requests in 2011, with 75 percent compliance. Facebook does not provide such information.

In response to criticism from civil liberty groups, social media companies are starting to add policies that they will notify a user when a

request for information has been made, prior to handing the information over to authorities. Social media companies have also begun to fight against government requests for user information. Accordingly, some courts have drawn a line between protecting the privacy of some information (e.g., private posts, private messaging, and private pages), while not protecting others (e.g., information that is open to the public or shared with others).

The Fourth Amendment's protection against government search and seizure is based upon "reasonable expectation of privacy." This expectation is based upon whether or not society wants to protect a specific realm as private. For example, the United States has decided to protect a person's home as a realm of privacy. However, as media technology has advanced, what society considers private has narrowed. Recent cases in U.S. courts have shown that the nation is not ready to allow for all aspects of life to be intruded upon, just because technology can do so. Similarly, as social media becomes more ingrained as a part of everyday life, society may decide to protect that realm as a forum with a reasonable expectation of privacy.

Search Engine Bias/"Google Bias"

Media scholars are increasingly problematizing the idea that search engines are neutral technologies or tools. In 2004, Helen Nissenbaum and Lucas Introna carefully traced the way in which bias occurs in search engines, and paved the way for a host of studies on the social and civic impact of monopoly search engine power on businesses and the public. The term *Google bias* has come to be known as a way of characterizing the how Web site ranking through Google's algorithm has the effect of prioritizing its commercial interests over its competitors. This bias is attributed to a host of factors that are a part of algorithmic or computational decision-making processes. In 2003, John Battelle and Alex Salkever introduced the term *Googlization* to characterize the search engine's dominance on the Internet. Siva Vaidhyanathan extended this definition to reflect the expansion of Google's control over public information, books, media, and information and communication technologies (ICTs). Alex Halavais argues that the emergent search engine society has dire consequences for the future of democracy and the public.

Technologies are designed to bias and discriminate among types of information, in that they sort and categorize as part of their inherent logic. Oscar Gandy, Jr., discusses how technology discrimination, which can include search engines causes disproportionate harm to certain segments of the population that are already on the social, political, or economic margins. Corroborating this idea, two separate studies by LaTonya Sweeney and Safiya Umoja Noble brought attention to the ways that search engine bias in Google misrepresents African Americans by biasing advertising and content. In 2012, Sweeney showed how Web searches on African American-sounding names were more likely to produce advertising and Web sites for criminal background checks than white-sounding names. That same year, Noble showed how searches on women and girls of color, particularly black girls, Latina girls, and Asian girls were likely to favor pornographic, adult-themed, and hypersexualized Web sites and advertising.

Search Engines and Elections

In the realm of politics, Robert Epstein and Ronald Robertson conducted a study for the American Institute for Behavioral Research and Technology on the effect of search engines in election results. In 2013, they discovered that more than 50 percent of democratic elections could be biased toward one candidate or another through search ranking of favorable and unfavorable Web sites for political candidates. They argue that the public would not be aware of the process of search bias because it is embedded in the structural placement of positive results on the first page of search. Epstein argues that search engines hold such power and prominence in control of information that they are a threat to democracy with their undue influence on politics. Results of their study show how a search-engine company could influence the outcome of elections with no challenge and with no public knowledge of its practices. As a result, they argue that search engine companies must be closely regulated because of the monumental impact they can have on controlling politics.

Criticism of Google

Recent reports like ConsumerWatchdog.org's Inside Google report, "Traffic Report: How Google is Squeezing out Competitors and Muscling Into New Markets," of June 2010, details how Google effectively blocks sites that it competes with and prioritizes its properties to the top of the search pile (YouTube over other video sites, Google Maps over MapQuest, and Google Images over Photobucket and Flickr). The report highlights the process by which "universal search" is not neutral, and therefore it is not a universal process, but rather a commercial one that moves results for Web sites that buy paid advertising to the top of the list.

Many critics of Google have been enhancing efforts to provide data about Google's commercial practices to the public, and the U.S. Federal Trade Commission (FTC) investigated everything from its Wi-Fi data harvesting of consumer data to its horizontal ownership and dominance of Web-based services like YouTube, AdSense, GoogleMaps, Blogger, Picasa, Android, and Feedburner. Ultimately, in 2012, the FTC determined that no consumer harm was at play in Google's

biasing of search results. Nevertheless, critics of Google and the changes implemented on its algorithm named Panda persist. These challenges include concern over Google's decision to target "low quality sites" that allegedly deprioritize original content creators' sites in its ranking. As a result, complaints have been lodged with search engine public interest groups about the loss of placement status and Web traffic, while news and social networking platforms, along with Google's companies, have significantly moved up in Web site ranking. Google's search enhancements are designed to penalize Web sites that overoptimize in an effort to game the system and move up in rankings, particularly sites that are duplicative of others or are too general and nonspecific to be a meaningful content contribution to the Web.

Search engine bias is leading to discussions about regulation, which has already begun in the European Union. Several conditions, such as clear labeling of Web sites and ads promoted, as well as inclusion of competitive sites, are under discussion between the EU and Google. Competitors and other interested parties and scholars are proposing regulation of search engine bias in Google, among a host of other conditions, that will limit the search engine giant's monopoly control over ad placement and Web indexing practices, and include rival search engines in search result displays.

Search Engine Data (Use in Social Media Campaigning)

Social media have begun to contribute to political campaigning. They are useful tools for politicians to share opinions with the general public. Politicians can also use social media to spread their messages in an effective way. Social media is used as a launching pad for election campaigning by parties through their Web sites or profiles in different social networks. Help from technological experts is the fastest and targeted way to reach many people in the right way. At the same time, they can provide simultaneous feedback from people and improve communication. A social media campaign in politics uses search engine optimization (SEO) as a strategy, looking at public opinion about the candidate, influencing people's opinions, communicating points of views about candidates, and making sure that people looking for information on issues and elections find the candidate's site.

In addition, canny media strategists have developed techniques for co-opting the seemingly neutral search engine function through the purchase of paid ads that contain significant words or phrases pertaining to their candidate or issue—"keywords" in the nontechnical sense of that

expression. The presence of these planted key words eventually improves the likelihood of that candidate or issue making it to the all-important first page of organic Google searches by the unsuspecting public, thus increasing overall awareness of the candidate or issue, and creating the perception that it/they occupy a more prominent place in public affairs or the political arena than may actually be the case. Finally, an especially troubling vulnerability of SEO “neutrality” is illustrated by the ease with which it can be subverted by a small but determined set of users who lard the Web with malicious and sometimes false information that has been linked to a person or issue who they would like to damage or destroy.

Because keyword searching has no relationship to fact checking, it is surprisingly easy to distort public image through creative SEO manipulation, as illustrated by the case in which Rick Santorum, a Republican presidential candidate, found that his name had been deliberately recast as the description of a socially provocative sexual act by a gay rights activist who he had offended through his disparaging public remarks about the lesbian, gay, bisexual, and transgender community. The ersatz word *santorum* was then pushed to the top of the Google SEO list by the sheer volume of material posted on the Internet, primarily through a dedicated Web site and blog devoted to the exercise. Although Santorum’s predicament was labeled as his “Google Problem,” many writers report similar things happening to him on other search engines. Social networks are a new way of communicating, where the old communication paradigm is obsolete, where the unidirectional model is replaced by a multidirectional one. Everybody can communicate and build the message, not just listen, interacting in a free way and deciding who to interact with. In 2008, Barack Obama’s campaign started the networked era in political campaigning. Social networks were used as a participatory place, interacting with citizens and considering them part of the campaign.

Search Engines

Search engines are programs that search documents for specific keywords and return a list of documents where the keywords were found. When the term is used in relation to the Web, it refers to the form that searches through databases

of HTML documents. A search engine is also software that uses applications to collect information about Web pages. The information collected is usually keywords or phrases that are possible indicators, including URLs, codes, and links. That information is then indexed and stored in a database. Search engines are always adjusting their algorithms, and practitioners are constantly trying new strategies and modifying their approach. The value of the site is not just the site’s content, but also social media signals and site traffic patterns. Not every search engine uses the same algorithm to search. The algorithm is how the search engine evaluates the relevance of the information.

When one queries a search engine to locate information, one searches through the index that the search engine has created, not the Web. These indices are giant databases of information that is collected and stored, and subsequently searched. Different search engines produce different results because not all the indices are exactly the same. It depends on what the “spiders” find or what humans submit. It is necessary to have an SEO plan in order to reach SEO goals; these goals are constantly changing. These days, a few search engines focus on a single aspect of SEO. This means that candidates must improve their strategies more than with simple keywords or links: The strategy must be dynamic.

Social Media Campaigning

Many citizens just use social networking sites for entertainment. Even if they visit online political content, they most likely have an initial interest in politics, a party, or a certain politician, according to J. Brundidge and R. E. Rice. People use social networks in a social way, and that is a good reason to connect people with parties. Social networks do not work alone, and other media are still very important. However, since the mid-1990s, the Internet has become an important means of political campaigning, and was first extensively used in the United States. Also, these online resources have changed the way that fundraising takes place. Obama’s Twitter account reports over 14 million followers. These social networks close the gap between politicians and citizens. Another example was the Internet Roh Campaign in 2002 in South Korea. Web 2.0 is a community resource. The Web is built for user-generated content. Also,

smartphones and other devices connect with these platforms and can share content and make social networking easier.

The use of social networking for campaigns requires technical expertise and specialized design knowledge. Users express their likes or dislikes to others through a debate or exchanging points of view. Social media is also useful to create political awareness among the masses. Campaigning through social media is cheap and cost effective. Recent developments in Web campaigning in the United States have confirmed the importance of social networking use to reach a core target or specific goals. The Web campaign provides insight into the wider campaign logic and future developments. It provides an unmediated and representative portrait of campaigns, and it is useful to improve marketing strategy in a more individual way, changing the approach in a dynamic way in order to build a better relationship with the people. This way of making political strategy allows increased visibility and interactivity and answers citizens quickly. It can also help people to understand political messages in an appropriate way and to perceive politicians as more concerned about their personal lives. New technologies allow a microtargeted approach to voter contact, called micromessaging. Adaptation to the online environment, rather than further centralizing parties, opens them to a more networked model of organization, and can better connect parties with social movements. Barack Obama used it to improve his grassroots strategy through volunteer participation. Volunteers were trained and monitored the campaign. Obama's strategy was also redirected by a digital hub developed created by Facebook in 2007; the site allows supporters to join the campaign using only an e-mail address.

The total signed by Election Day was over two million, with 200,000 events organized offline, and 35,000 groups created. A new era in political campaigning broke with the traditional model. This was effective because it worked as a net, in a decentralized way, and volunteers at local places connected better with citizens in ways that were not possible before the digital age. They worked autonomously. It also meant that more people could be involved to collaborate and connect in a more intimate way. Obama connected with cyber-activist movements. People felt involved with the projects and wanted to collaborate, forming

groups through different interests and lifestyles, but joined by the candidate.

The report on politics and social networks affirms that 94 percent of politicians ranked the utility of social networks as "outstanding," and that 78 percent believed that the networks were an excellent way to reach citizens. However, the use of social networks as a central axis of their campaigns was ranked as "outstanding" by only 17 percent of participants, whereas 79 percent ranked them as "remarkable," according to M. Túñez. Consumers have changed, they are more critical, demand more information, and expect to have it at every hour of the day. Consumers have more expertise and know if the communication is real or false. The link is based on trust. All users are interconnected and create messages. They decide what they want to see and when, so candidates must take part in the conversation, knowing these particular aspects.

Politicians must listen to the people to build a better reputation, not just with a discourse or a program, but also to build a long relationship based in the truth and for the future, creating a real brand and valuing their comments. The way of doing that is also important, not just by creating blogs, but also with profiles and a real multidirectional model, communicating collaboratively, sharing the effort with all who take part in the campaign.

Search Engine Optimization

Search engine optimization (SEO) is a common procedure that involves designing or modifying a Web site in order make it appear in search engine results more frequently, more prominently (i.e., closer to the top), and in response to a wider range of potential search terms. Like many Web-related phenomena, SEO techniques are constantly changing to accommodate the Web's developing technologies and exigencies. Today, according to the Pew Research Center's Internet and American Life Project, a 10-year survey following Web use practices from 2002 to 2012, most Web users access online content by first using a search engine. Their study found that search has remained one of the most popular of all Internet activities. Accordingly, a Web site that optimizes for search ranking can draw many more visitors than one that does not. Scholars such as Laura Granka; Victor Asal and Paul Harwood; and Lucas D. Intronas and Helen Nissenbaum have argued that the powers of search engines and their optimization have political stakes that Web users ignore at their peril.

As more people rely upon the Web for information, communication, entertainment, and commerce, search engines are becoming increasingly influential gatekeepers to the resources that millions of users seek online. Search engines use complex search algorithms that can grant or deny access to resources that users may not otherwise be aware exist. In this capacity, they are primary access points to the treasured resources accessible to those who use the Web; moreover, their incredible power to delimit access also influences the capital advantage that individuals, organizations, and companies with Web sites stand to gain when their sites are visited by more people.

Laura Granka has argued for more transparency on behalf of search engines and their algorithms to make the political playing field more level. For instance, Web users and designers alike might want greater exposure to information and content that search engine optimization could conceivably grant if search algorithms were made more transparent. Victor Asal and Paul Harwood have similarly called attention to the political ramifications of search engines' growing power, and the resultant higher stakes of their optimization: "Any feeling of virtual sovereignty, or perception that the Internet is an egalitarian space, is quashed when the mechanics of search engine algorithms are unraveled. Search engines are not egalitarian." From this perspective, SEO (though legal) has the capacity to privilege some Web sites over others. The process of optimizing a Web site for a search engine, therefore, can be seen as a political act.

Search Algorithms

Though specifics of search algorithms are not always made public, they generally take as input a sequence of words (search terms) and return as output links to Web pages that evaluative criteria (algorithms) indicate contain the best encapsulation of the information the user sought. Because search terms can be ambiguous, applicable to multiple subjects, or because two people looking for the same information might enter substantially different search terms to find it, search engines need to develop very particular sets of rules whereby they translate inputted search terms into proper directions to locate the requested information. Search engines operate by

first creating a database, or archive, that associates Web pages on the Internet with information. This process involves “crawling” the Web with computer programs sometimes referred to as “spiders” that visit Web pages and index the information in a database. Search engine algorithms must then identify, from a search’s textual input, what exactly it should select from its archive of the Web to return as output. These algorithms must decide, from the multitude of Web pages that contain some or all of the search terms, which to rank higher and which to rank relatively lower in the output. The decisions a search engine makes in this process inevitably privilege some information at the exclusion of other information, making the effort of SEO a political struggle for inclusion.

Even slight differentiation in these choices can lead to significant differences in search results. It is not uncommon, then, for one search engine to return different results from another search engine given the same search terms. This phenomenon reflects not only a search engine’s different restrictions and algorithms, but also the SEO techniques that a given Web site employs in relation to a particular search engine’s parameters. Optimization techniques, therefore, often involve targeting a specific search engine’s known rules for finding and ranking online content.

Commonalities

Though different search engines follow variable criteria to help them crawl the Web and identify relevant information, common elements exist across search engines, giving practitioners of SEO a basis for better optimization strategies. In particular, SEO commonly involves a variety of techniques and procedures associated with strategically changing or influencing the user-accessible content of a Web site or the parts of a Web site that a search engine sees, but users do not. As search algorithms evolve, the meaningful SEO techniques also evolve. Though it was once thought optimal to modify metatags contained in a Web site’s code in order to enable a search engine to classify and categorize the site in particular ways, such as according to its keywords, title, and description, this process proved susceptible to manipulation by “spamming,” so many search engine algorithms no longer privilege metatags as much as they once did. Though

title and description metatags tell a search engine how a site characterizes itself (therefore these titles and descriptions still appear next to a link in actual search results), other more substantial factors are now thought to be more integral to SEO. In particular, search algorithms are thought to value, among other factors, the following properties of a Web site: freshness of content, apparent authority and trustworthiness, number and quality of inbound and outbound links (i.e., links going to and leading out from a Web site), and both connectivity with, and popularity among social networks

Web sites such as the *Huffington Post*, well known for appearing widely in search results, rose to prominence in the latter half of the 2000s by aggressively pursuing these and other SEO techniques. The phenomenon of “Google bombing” is another example of how aggressive pursuit of SEO techniques can powerfully influence the results of a given search. The political ramifications of such enterprises are made especially evident in the Google bombing of former Republican U.S. Senator Rick Santorum. Angered by Santorum’s public comparison of homosexuality with bestiality, gay-rights advocate Dan Savage easily used available SEO strategies to alter what results came up first in a Google search of “Santorum.” Instead of calling up the conservative politician’s Web site, the top-ranked Google search results offered a lewd definition of “santorum” related to a sex act.

Seattle 1999 WTO Protests

The Battle of Seattle refers to the protests that took place in Seattle against the third World Trade Organization (WTO) Ministerial Conference from November 29 to December 3, 1999. Considered the first global protests between the hegemonic globalized order and the alter-globalization social movement, as well as a relevant episode on the configuration of the latter, the Seattle anti-WTO protests are also an example of a social movement's appropriation of information and communication technology for activism. From the first call for the protests, information and communication technologies were widely used by participating organizations for planning, organizing, articulating, and making it visible.

The wide repertoire of cyber-activist strategies and Web-based actions put in practice by organizers and protesters included the broadened use of e-mail, alternative and counterinformative Web sites, discussion boards, virtual sit-ins, and shadow/fake/spoof sites. The articulation of offline and online actions during the Battle of Seattle explains why it is highlighted as a foundational event when analyzing how the Internet has influenced social movements' tactics and actions.

According to different sources, between 50,000 and 100,000 people participated in the protests. On the opening day of the meeting, tens of thousands of protesters took over downtown Seattle, occupying the streets. They intended to shut down the conference by surrounding the WTO conference site, forming human barricades to block traffic, and controlling street intersections so that delegates could not cross from their hotels to the convention center. Participants displayed a wide variety of artistic practices, including dancing, playing music, drumming, creating giant puppets, costumes, street theater, huge balloons, and large banners with anti-WTO messages.

The Internet was used as a permanent source of information about the situation on the streets and police tactics, updated by protesters who were onsite and connected to the Web, and shared through e-mail, networks, or alternative Web sites. At the same time, specifically Web-based actions were developed. Thousands of e-mails requesting information were sent by activists to the WTO site, causing the crash of its server, and a virtual sit-in was organized. A virtual sit-in consists of simultaneous, continuous access to a specific Web site by many users, aiming to generate a huge amount of traffic on the site, and discouraging people from accessing it because of its slow connection response. From November 30 to December 3, it is estimated that more than 450,000 people inundated the WTO site, making the WTO's server unavailable for certain periods and the conference server intermittently very slow.

Although nonviolent action predominated, some individuals, in a formation known as Black Bloc, engaged in property destruction and acts of vandalism, breaking corporate chain-store windows, vandalizing storefronts, and painting graffiti at targeted businesses. This produced confrontations between protesters and the police, who charged against the protesters, shooting rubber bullets and pepper spray at the crowd and driving people out with volleys of tear gas. Hundreds of people were arrested, the city declared a state of emergency in downtown Seattle, and it set up a restricted access zone that protesters called a "no protest" zone, in what they considered a suspension of the basic rights of free speech and assembly. Publicized by worldwide media coverage, city

Police use pepper spray on the crowd during the World Trade Organization (WTO) Ministerial Conference protests in Seattle, Washington, on November 30, 1999. The Seattle anti-WTO protests were an early example of a social movement using information and communication technologies by employing e-mails, alternative and counterinformative Web sites, discussion boards, virtual sit-ins, and shadow/fake/spoof sites to organize their activism.

officials and police were criticized for mishandling the protests and for being unprepared for it.

Despite the declaration of the state of emergency, activists continued to engage in manifestations throughout the week, defying the restrictions until December 3, when the WTO meeting ended in failure because of the disagreement of representatives from undeveloped countries and small economies, who refused to be marginalized from the decision-making processes. Some activists and analysts have underlined the role of the protests in bolstering third-world representatives, who were also under pressure from social movements in their home countries.

Alternative and Shadow/Fake Sites

Contesting the corporate media coverage, which was criticized because of its emphasis on the violent acts of the Black Bloc, protesters created alternative Web sites, or what some authors have named the “shadow media.” Particularly important sites included WTOWatch.org and the Independent Media Center (IMC), or Indymedia, created during the Seattle protests. Indymedia became a large

global alternative network, with almost 200 local sites today. Based in a grassroots “be the media” model of journalism and an open publishing system, the IMC broadcast real-time and multimedia coverage (with video, audio, text, and photos).

The cyberactivist repertoire also included the creation of shadow or fake Web sites. Techniques such as “culture jamming,” the alteration or parody of corporate advertisements through the use of artistic techniques such as collage, appropriation, humor, or irony, were used to spoof or cloak sites. The imitation of original Web sites was created by using a URL so close to the site’s real address that it could be confused with the original one, or by producing a graphically identical copy of it, but with different content. Usually used for imitating financial institutions or commercial sites, these false Web sites are considered a very effective practice in order to generate confusion or uncertainty among Internet users looking for the official Web site.

When used by fraudsters, a fake Web site can obtain a victim’s password or other personal data; if adopted for political or activist purposes—cloning, for instance, the sites of institutions,

multinational corporations, or politicians—then its aim would be to parody, disqualify, or provoke the original site's owners. There is a continuity among the use of costumes and puppets in street protests and the creation of fake or spoof Web sites on the Internet because in both cases, there is a particularly ironic and creative dimension.

During the Battle of Seattle, a shadow site was created on the basis of the official WTO Web site design. Named after the organization's predecessor, the General Agreement on Tariffs and Trade (GATT), the site (<http://www.gatt.org>) was set up by the group ®TMark (pronounced "artmark") in collaboration with other activists known as The Yes Men. Its content was completely different from that of the original site, and it included the announcement of the cancellation of the opening ceremony of the conference. Whereas the WTO official site used the logo of the conference as a hyperlink to the official conference Web site, the fake one linked it to anti-WTO material. On its homepage, the spoof site included imitation stories and quotations from WTO official, with ironic or cynical "helpful" commentaries. It even warned about a "fake WTO Web site" that was misleading the public, linking to the original WTO site.

Cyberactivists created another spoof site, replying to the official one (<http://www.wtoseattle.org>) launched by the Seattle WTO official host committee for offering live casts of the sessions and trade symposiums held as part of the meeting. Using an identical, but inverted URL (<http://www.seattlewto.org>), the fake site featured information on protests and the negative consequences of trade globalization. The WTO reacted angrily, releasing a press statement that deplored these practices, qualifying it as illegal and unfair, and denouncing that it interfered with the public's right to gain access to WTO information.

Anti-WTO fake sites created during the Seattle protests became a real challenge to the Web visibility of the official site: Not only Internet users widely accessed the fake Web site, but even some search engines directed users to it, rather than to the official one, because of its numerous references to the WTO. Besides this, some approaches underlined that WTO's supposed transparency was put into question, and its reaction produced great attention from media coverage to the groups behind the fake site.

Generally, the effectiveness of a fake site is associated with its appearance and quality because it will increase a user's trust, but when used as a cyberactivist tactic, its successfulness is difficult to evaluate. Colonization of domain names (of institutions, companies, or politicians), the irritation produced targeted institutions or politicians, the cost in time and money of prosecuting the site's maker, the global visibility of the action, and the use of satire and irony to advertise claims and denouncements are pointed out as some relevant effects of shadow sites as a cyberactivist tactic. At the same time, this practice sets some legal challenges. Property laws are questioned, and its unclear points are exploited through the appropriation of domain names, which are purchased by activist groups to launch spoof sites.

The use of irony and playing with the ambiguity between authenticity and simulacrum that characterize fake Web sites are also coherent with postmodern principles and symbolic forms of resistance, as well as with the global and virtual scenario of the World Wide Web. While mainstream opinions emphasize a negative vision of this, referring to it as a "hoax" or "fraud," an alternative perspective argues that this ironic visibility and ambiguous effect become central for the political message that motivates this cyberactivist action and the production of the cultural profit it aims to cause, which depends on reaching the widest potential audience, as well as on computer skills and the creative techniques used. In this sense, shadow or fake sites created during the Battle of Seattle are considered part of the relevant contribution made by the significant use of information communication technology during the protests.

Second Life

Second Life is an online virtual world created by Linden Lab and launched in June 2003. It was intended as a space of limitless possibility enabled by virtual reality, informed by the libertarian "Californian" ideology that imagines cyberspace as a place of stateless personal freedom. User avatars (or "alts") can be remade in ways that are only restricted by the imagination of users and the technical limitations of Second Life. The environments and objects that populate Second Life are created not by Linden Lab, but by Second Life's users. Second Life has an economy and a currency. Users are allowed to produce and sell commodities in a basic market economy.

The libertarian ideology and free-market economy of Second Life, combined with its massive increase in global popularity in the mid-2000s, consequentially led to a number of political issues regarding identity, economy, and governance in virtual worlds as "real world" laws and economies increasingly intertwined with the regulation of online media. While Second Life is no longer as prominent as it once was, the debates that it inspired are still essential for understanding the political and legal challenges confronting social media and virtual worlds.

Identity Politics and Sex in Second Life

Because Second Life is based around avatars, users possess some level of anonymity, permitting experimentation with the possibilities of identity. Users who may be disabled, for instance, can perform selves that may escape the prejudices they

encounter in real life. The possibilities for identity in Second Life include the creation of genitalia for avatars and scripted animations that represent sex. These enable users to explore their sexuality in a way that may be otherwise prohibited in their lives beyond the virtual, engaging in bondage, domination, and sado-masochism (BDSM), prostitution, and virtual pedophilia (or "age play"). Sexual experimentation in Second Life is one of its most controversial aspects.

What may be legal to view in one country may be a criminal offense in another. Just who is engaging in sexual activity online, and the legality of their behavior, is unclear given the anonymous nature of avatars and the "virtuality" of online interaction. As Linden Lab has acquiesced to a number of governmental requests to regulate sex, users have often found identities and behaviors stigmatized through governmental, legal, and cultural norms likewise stigmatized online.

Economics of Second Life

Second Life, unlike many other virtual worlds, has actively encouraged economic activity from its inception, instituting a currency, the "linden dollar," that is easily exchanged with U.S. dollars. Capitalism is integrated into Second Life through the licensing of land and the exchange of digital objects and services. While access to Second Life is free, virtual labor, production, and consumption are often essential parts of the Second Life experience. Users regularly find employment online in occupations such as fashion design, land speculation, or sex work.

As with sex, there are legal and political implications that arise from Second Life's economy. In 2006, over \$1 million was reportedly exchanged in Second Life each day. One user claimed to possess the equivalent of \$1 million in digital assets. At least 58 users were making more than \$60,000 per year. The ability to work full-time online leads to concerns about taxation and regulation. Because users of Second Life are geographically dispersed, it becomes difficult to identify how and where this economic activity should be regulated. While Second Life collects Value Added Tax from its users who live in the European Union, there are also methods that users employ to avoid regulation from governments beyond the virtual world.

These questions of economic regulation are made even more complex considering how Linden Lab, through its terms of service, effectively claims ownership of everything that exists within Second Life. While personal liberty and private property are often assumed by Second Life's users, any violation of the terms of service can result in one being banned without any way to access digital assets. Likewise, there are no technical limitations to theft or unauthorized copying in Second Life because of the nature of digital commodities. This point was exemplified by the "CopyBot Affair," in which a program produced endless copies of objects. While users assume ownership of their intellectual property, they have found that they are powerless to defend their private property from digital theft.

Campaigns, Protest, and Second Life

At the height of its popularity, Second Life attracted the attention of political campaigns, with candidates establishing official or unofficial campaign centers there. Consequentially, Second Life has also been a space for conflict between politically engaged digital citizens. Notably, Second Life was home to a riot between supporters of French politician Jean-Marie Le Pen and others in Second Life who organized to protest the racist policies of Le Pen's party.

Other forms of protest in Second Life have met with resistance from Linden Lab, especially users' criticism of Linden Lab and their management of the virtual world. As Second Life ostensibly has no government, dispute resolution and "law enforcement" are often assumed by ad hoc groups of particularly engaged users. However, Linden Lab still serves as a governing body that resolves disputes through an often arbitrary application of rules. Because of the libertarian beliefs of users and the supposed libertarian mission of Second Life in general, this haphazard form of online governance, combined with the sporadic incorporation of regulations from national governments, opens up questions about the relationship between national governments, Internet corporate governance, and the rights and regulation of users and avatars.

Secondhand Political Engagement

In the last decade, there have been important shifts in the way that the component agencies of many national political systems go about the business of producing political publicity. Scholars L. H. Hoffman and T. L. Thomson have posited that political efficacy would positively mediate the relationship between TV viewing and civic participation, while political cynicism would negatively mediate this relationship, and internal political efficacy did indeed mediate the relationship between late-night television comedy viewing and civic participation, as well as local television news viewing and civic participation.

Traditional and social media are also good examples of firsthand and secondhand information: Rather than secondhand narratives, television provides a moving visual panorama of political events, and newspapers primarily work through the written reports of political events produced by journalists, with politicians' words featured at points, but necessarily secondhand. Thus, one can say that the majority of our information is secondhand, and is written with a very

specific ideological bias. For example, the fact that a large proportion of Latin Americans have never traveled to the United States suggests that most of their opinions may be based upon the secondhand information they get from the news about the United States, and not from firsthand information from having spent time in the United States.

People in markets with more political ads and candidate appearances are more likely to discuss election-relevant topics with other people and build their knowledge base. They are more likely to gain political knowledge from exchanging secondhand campaign information with other people. The relationship between political discussion and knowledge is strengthened in a market with more televised ads and candidate visits than in places with fewer ads and visits: Visual evidence reaches audiences faster than verbal information. Instead of secondhand narratives, television offers visuals of political events; while radio removed the prerequisite of literacy, television reduced the importance of language. While addressing audience members as individuals in their own homes, and achieving a new level of intimacy and individuality in the political relationship, contemporary television systems have added visual performance to this development, making television, in some respects, a theater of political performance, which is simultaneously a theatre of voices, faces, bodies, and actions.

Scholar T. M. Holbrook proposes that although campaigns influence public opinion, the process that underlies this influence remains somewhat a mystery, and the most reasonable explanation for campaign effects is that campaigns influence public opinion by generating persuasive information—information that, once acquired, has the potential to move the electorate in one direction or the other. It is reasonable to believe that candidates are consistent across different venues in the themes they stress, but there is no guarantee that they are. In general, to examine the effects of a campaign, one needs a more comprehensive view.

One may gather estimates of the nature of the campaign from newspaper accounts, such as descriptions of political advertisements broadcast by different candidates, and reports of a wide variety of other campaign activities. All of that is

secondhand, relying on the judgments of political reporters. Because the majority of people are not personally involved in politics, most of what individuals know about the political environment comes via the mass media; in this way, the political world comes to people as a secondhand reality, helping to form not only individuals' first political cognitions, but changing them over time, Hoffman and Thomson note. People relate more profoundly to, and are more apt to remember, vivid images rather than human speech, no matter how eloquent or accessible.

Perhaps more importantly, even though political socialization begins in preschool years, understanding of abstract political issues is not likely to occur until adolescence, when young people are more cognitively developed. Because adolescents are able to think more abstractly and less egocentrically, their potential for understanding politics and news programming is greatly increased over that of younger children.

Citizens' responses to satisfaction surveys are disproportionately influenced by a small number of "visible" services, perhaps supplemented by secondhand evidence from media reports; however, insofar as making sense of service improvement requires people to interpret and negotiate a secondhand range of information—expert, social, and mass media, as well as personal experience—different patterns of response between social groups are to be expected, with some feeling better informed and others feeling further alienated, both by the difficulties of understanding the information, and ambiguity or powerlessness in knowing what to do with it, Hoffman and Thomson note.

They also state that social scientists in the last half century have become increasingly interested in what motivates and socializes people into becoming active citizens of a democracy, and that much of this interest stems from observations about the decline in key indicators of an active citizenry, including behaviors such as voting and other forms of political participation, as well as affective dimensions such as confidence in government and trust. For instance, while social trust belongs to the private sphere, reserved for attitudes toward individuals, and is a feature of personal relations based upon firsthand experience and knowledge, confidence belongs to the public,

political sphere and is built upon secondhand sources, particularly the mass media.

Informed Voters

Access to truthful and valuable information can be limited by lack of accuracy in the media. Sensationalism and shock value are also common components of newspaper front pages or evening news reports; for this reason, it is easy for people to draw conclusions about others when their information about others is secondhand or incomplete. While there is a tendency to assume that social and political trust are different sides of the same coin, they are logically different, and because the former is built on personal knowledge, political trust is built on secondhand sources, for example, the mass media. Social trust belongs to the private sphere and is a feature of personal relations based upon firsthand experience and knowledge; political trust belongs to the public, political sphere and is built upon secondhand sources, particularly the mass media.

While voters can certainly pick up information about political debates via the mass media and from interpersonal communications, it should be expected that debates are more useful sources of information to those who actually watch them than to those who pick up the information secondhand, Holbrook notes. He also states that those who are most directly exposed to political information are the most likely to benefit from the information, highlighting the importance of political engagement and the problem inherent in efforts to share political information with the masses; simply put, even for high-visibility events such as debates, the learning benefits accrue most directly to those who are already politically engaged.

Uninformed and disengaged voters—those who could potentially benefit the most from campaign information—are not sufficiently exposed to the political messages, and therefore do not gain as much information from the campaign as the politically engaged. Democracy assumes that its citizens have enthusiasm and organization to have an effect on society through established political processes. Hoffman and Thomson propose that democracy is not exactly a natural state of being; instead, it consists of habits and competencies that require skills that must be acquired, and these skills are obtained (or, arguably, not

obtained in many cases) through the primary socializing agents of school, family, and the media.

Selective Exposure

The study of selective exposure to information—defined as a media choice behavior, whereby individuals tend to favor information that confirms pre-existing attitudes and beliefs while avoiding contradictory information—is an important area of study in media and communication research. Historically, the idea that individuals choose to attend to information that resonates with their pre-existing attitudes and beliefs, or avoid inconsistent information, has been explained primarily in terms of Leon Festinger's cognitive dissonance theory. According to this theory, cognitive discomfort or dissonance arises when an individual experiences cognitions that conflict with each other. By extension, in order to preempt or alleviate cognitive dissonance, individuals are

motivated to seek out agreeable information and avoid information that is incongruent with established attitudes and beliefs. When applied to a political information context, this means that individuals are motivated to seek out information that is congruent with or confirms their political and/or ideological attitudes and beliefs while avoiding conflicting information. This pattern is what has led some communication scholars to conclude that the media often serve to reinforce, rather than change one's beliefs.

Trends in Selective Exposure in Online Environments

While the study of selective exposure has been a staple of mass communication research for decades, it has recently seen renewed interest because of the ever-growing trend in online news consumption. The Pew Research Center reports that more Americans now turn to the Internet for regular news consumption than newspapers and radio. This new pattern of news consumption raises some important questions concerning the kinds of content that users are exposed to. Not only has the Internet fostered the proliferation of information sources, but by many accounts, it has further spurred the rise of increasingly partisan sources. In order to navigate vast bodies of information encountered on the Internet, online users are forced to select specific content and sift out unwanted information. Online news consumption depends on users' self-directed content selection.

For these reasons, some scholars argue that the Internet fosters environments conducive to the pursuit of content that suits users' informational needs, and many fear, their pre-existing political attitudes and beliefs. These environments, scholars argue, are facilitated by the filtering affordances embedded in a wide array of Web interfaces (from search engines to portals to blogs), and serve to exacerbate the well-documented human tendency toward selective exposure to political information.

Several studies have empirically documented evidence of selective exposure or ideological filtering in media use: Conservatives and liberals alike have been shown to favor information sources and content that resonate with their pre-existing ideological attitudes and beliefs. This preference is manifest in either selecting partisan news

sources when the source is salient, or in choosing to attend to attitude-consistent political messages when the news source is not salient. For example, in a study examining users' selective exposure to online news sources, findings indicated that users' political orientation was an important driver of news selection and avoidance. Specifically, Republicans showed a strong tendency toward selecting traditionally conservative news sources (e.g., Fox News), while Democrats showed a propensity toward avoiding such sources. Likewise, a study examining users' exposure patterns to attitude-consistent or counter-attitudinal news stories found that users preferred attitude-consistent over counter-attitudinal stories, which ultimately reinforced their political self-concept (i.e., personal allegiance to a political ideology).

In contrast, another body of research paints a more complex and nuanced picture of selective exposure and avoidance patterns. Most notably, a study conducted by Pew Internet Research as part of the American Life Project found evidence that, at least in an electoral context, Internet users appear to exhibit greater exposure to political information, and do not appear to discriminate between agreeable information and content that is in conflict with their pre-existing attitudes and beliefs. Research has further shown that while Internet users might actually favor opinion-reinforcing political information, they do not necessarily avoid conflicting information. This particular trend was recently corroborated in the context of Twitter interactions, with some studies suggesting that while Twitter users are more likely to engage in information exchanges with others who share their political views, they are also actively engaged with users whose views are at odds with their views.

These inconsistent findings may be at least partly because of factors like individual differences and type of online environments, which are not always taken into account. First, users who feel strongly about a particular issue show generally high levels of political interest, or have strong affiliations to a political party/ideology appear to in fact welcome exposure to information that challenges their perspective. These individuals see value in attending to opposing viewpoints, likely because they see it as an opportunity to become more grounded in their position, or to develop

more effective counterarguments. Next, research suggests that while selective exposure and avoidance may be the norm in political forums, where discussing politics is a central focus, they are not commonly observed in online environments where political topics are incidental (e.g., forums and discussion groups on more general topics). This particular trend is apparent in early CMC research, showing evidence for political conversation involving diverse viewpoints and perspectives among Usenet, real-time chat, and message board users, in particular, and by more recent findings indicating that online users have been shown to be more likely to engage in selective exposure, particularly when it comes to highly partisan information sources like blogs and niche political Web sites.

Last, the picture becomes even more complex in the context of exposure to political news via social media. Recent selective exposure theorizing posits that social endorsements—a distinct feature of many social media outlets—are poised to fundamentally reshape the way that news is consumed and shared on the Internet. For example, a recent study showed that social endorsements were a much stronger predictor of news selection than partisan sources, such that the mere presence of social endorsements reduced partisan selectivity to insignificant levels. To the extent that individual online social networks display a certain degree of political heterogeneity, social media shows notable promise in diversifying individuals' exposure to political news and information.

Effects of Selective Exposure

While the vast majority of selective exposure research has sought to document exposure and avoidance patterns, a less extensive but important body of research has focused on examining the effects that selective exposure and avoidance might have on the political system. An early, dire warning in this arena was issued by Sunstein in his seminal book *Republic.com*, where he argued that the greater opportunity for selective exposure to information on the Internet would likely result in the emergence of “echo chambers,” and ultimately extremism and polarization. Sunstein's echo chamber phenomenon refers to online environments where people congregate with others

whose political attitudes and opinions mirror their own. These environments, he further suggests, are a breeding ground for group polarization and extremism. Specifically, as a result of within-group discussion, individuals are likely to hold even stronger views than the ones they started with, and when these views are problematic, they are likely to manifest increasing hatred toward those espousing contrary beliefs.

Unlike the debate over the prevalence of selective exposure and avoidance, where the jury is still out, there is more definitive consensus regarding the outcomes of partisan selectivity. There is little disagreement that selective exposure and avoidance have undesirable consequences for a well-functioning democratic political system. Healthy democracies thrive on political talk and discussion—not only of the within-group, homogenous kind, but of the cross-ideological and heterogeneous sort as well.

Available empirical support confirms that selective exposure to information in online and social media environments encourages within-group political discussion, ultimately leading to increased attitude polarization and extremity. However, despite the robust pattern attributing polarization and extremity to selective exposure and avoidance in this research, the direction of this pattern is not always clear. There is at least one study showing evidence that political polarization drives selective exposure as much as the reverse.

Sentiment Analysis

Customers today have to choose commodities that meet both their current needs and possible needs among a plethora of products and services available on the market. Customer preference, which can be defined as the customer's choice of products or services, covers all activities related to the selection of one offer over another. Data on customer preference is important for organizations because possessing information on these preferences may help in predicting the likelihood of forming long-term relationships between companies and customers, and consequently, the chance that customers may select the company's product when a specific need arises.

There are various factors determining customer preference. They can be divided into ones strictly related to the product or service characteristics, and ones connected with the broadly understood product or service environment. When the product or service is taken into account, such issues as its physical characteristics (e.g., dimensions, colors, or shape), country of origin, functions, and price can be enumerated as the key factors shaping customer preference. It should be also mentioned that these qualities are not fixed, and their salience and strength depend on other issues. For example, price is often not the most important determinant in the case of selecting luxury products.

As far as the country of origin is concerned, the type of good determines the positive and negative associations regarding national producers. For example, some geographical places and their factories are associated with expertise in tailoring clothes, whereas other countries are said to create and manufacture the most reliable vehicles. It should be stated, however, that positive connotations can be quickly destroyed by some negative instances, both natural and man-made types, such as nuclear catastrophes, violation of human rights, negligence in production, and so on. In this case, proper crisis communication with stakeholders may stimulate the decreasing interest of customers in some offers. Informal communicative exchanges, especially those including such elements as rumor and gossip, can lead to the immediate fall of customers' interest in the product or service.

In a commodity setting, the determinants can be divided into micro (customer), meso (organization), and macro (business environment) factors. As far as the buyer dimension is concerned, such issues as income, personal needs, family status, ethnic origin, and national culture, among others, may determine the selection of products and services.

Organizational Aspect

In the organizational sphere, customer preference depends on one's satisfaction regarding the commodity offered by the company. It entails both the immediate content, connected with the postpurchase experience, as well as overall satisfaction. Customers may be satisfied with an organization's employees and its processes, as well as its products or services. The other important notion is trust because clients are likely to choose the companies that they have confidence in. The other factor is a customer's commitment to the organization. This can be revealed through personal identification with the organization, psychological attachment, and a feeling of belonging to a loyal and proud clientele. The level of trust and its influence on the choice of products or services are related to the domain or business that the organization represents. Thus, the role of trust will be higher in such industries as food or health because users ascribe more importance to a company's image and its past behaviors prior to their decision to buy a food product or health service than in the case of selecting many other types of products. Thus, companies operating in industries dealing with safety are more likely to be selected by taking the trust factor into account.

Analyzing the physical sphere of organizational life, such issues as office décor and artifacts determine customer preference. When the interior of an organizational space enhances positive emotions among potential customers, they are more likely to opt for the commodities or services offered by this organization.

Moreover, being recognized on the market is related to branding, and such issues as brand awareness and brand loyalty determine the selection of products or services. Customers do not only select brands they know well, but they are also likely to pay more for branded products and services. One of the reasons is that they have positive

expectations regarding several characteristics of the branded product or service, and consequently, they select the well-known commodity, even if it costs more than the competitive, unknown product. In the macro sphere, economic, political, and social situations on the national and international level shape customer preferences. For example, in times of crisis, some people do not purchase luxurious products or services, or they limit the consumption of other goods.

Customer Preference

Customer preference can also be studied by dividing one's choices into homophilous and heterophilous preferences. Homophilous preferences are related to the need to purchase similar articles to the ones selected and used by those people one lives or works with. On the other hand, some purchases are driven by heterophilous choices, since customers opt for products or services that can make them different, outstanding, or unique.

Customer preference can be examined by taking the notion of relationship into account. In the case of transactional exchanges, they involve small investment on both sides, and the relations are mainly economic. Thus, the relations may conflict because each side wants to achieve their aims. On the contrary, relational exchanges determine long-term and noneconomic exchanges between buyers and sellers.

The type of relations is determined by several factors. One is industry structure, since the attitude to contacts depends on customer and supplier concentration. Thus, the industries characterized by highly concentrated customer industries and fragmented supplier industries favor relational exchanges. Second, the approach to decision making in the organization depends on the type of department involved in decision processes. For example, if specifications are top priority, then the technological and engineering departments are dominant in the purchasing activities conducted by customers. Third, organizational structure, power relations, attitude to risk, and the cooperation between departments also determine the type of created relations. Moreover, the characteristics of purchases determine the type of established relationships. The goods that require postsale purchase are likely to create relational exchanges. The type of exchange selected is also

connected with transaction costs. Thus, both buyers and sellers opt for the exchanges that create rather low costs and relatively high returns.

In the methodological aspect, customer's selection often follows the facets of self-congruity theory. Thus, customers select products or services that are congruent with their system of values and their personal characteristics. The customer's attitude, and involvement in family and work, will determine his or her selection of products. Customer preferences can also be studied through the network perspective. Thus, the way customers choose and buy is determined by various grids and lattices, such as communication, innovation, or knowledge networks, present both on the side of the buyer and the customer. Thus, the role and strength of corporate networks and their influence on customer service determine the prospect's selection and purchase.

Obtaining Data

In the practice of obtaining data on customer preference, at least two methods can be enumerated. In the two-factors-at-a-time (or tradeoff) approach, customers are asked to display their preferences by taking a pair of attributes into account, for example by selecting the most and the least preferred alternative. In the full-profile approach, customers are requested to order their choices by ranking all the provided options. The method is selected depending on, among others, which parameters are interesting for market researchers, how many alternatives are compared, and which market sector is investigated.

Sentiment analysis offers the possibility to study attitude, by judging it as positive, negative, or neutral. Sentiment analysis is also important in modern social media, since people use blogs, discussion forums, and tweets to express their emotions, preferences, opinions, and feelings.

Sexting

In American politics, there has not been much of a divergence between public and private affairs for elected officials since the mid-1970s, when Watergate and Vietnam combined to erode public trust while spurring investigative journalism. Yet, there is a long history of American fascination with the sex lives of politicians. Presidentially, there are volumes examining, alleged love letters from George Washington to his mistress, Thomas Jefferson and Sally Hemings, Franklin Roosevelt dying in the arms of another woman, John Kennedy's stable of affairs, Jimmy Carter's lusting in his heart, and Bill Clinton's cigar exploits with Monica Lewinsky. Outside of the White House, congressional leaders have drawn national attention for many of the same exploits. Consider cases like that of Wilbur Mills (who chased the Argentinian Firecracker into the Tidal Basin), or Wayne Hays (whose lover Elizabeth Ray publicly

claimed to be unable to type, file, or answer the phone, despite remaining on the congressional payroll). Yet, today there is a new era of sex scandal wreaking havoc on the public sphere because of the advent and development of social media. The most widely known violator has been New York Congressman Anthony Weiner.

Anthony Weiner

While new technology brings with it vast potential for altering lifestyles for the better, it still produces negative externalities. While cell phones, Twitter, Facebook, and other sites have opened the doors for increased communication within society, they have also led to the Craigslist killer, the birth of *To Catch a Predator*, and pre-teens charged as sex offenders for distributing child pornography . . . of themselves. Without cell phones and social media, the world would not know what sexting is. One-quarter of American adults admit to sexting. This activity, which centers on the exchange of sexually explicit photographs and/or messages via social networks, text messages, and e-mail, has begun to have political ramifications in recent years.

Anthony Weiner became a prominent elected official in 2011, when he utilized Twitter to send a sexual photograph to a young woman from Seattle. When claims were first made that the photograph was sent by Weiner, he said that his account had been hacked and that he had not taken or sent the picture. However, after a few days of denial, he came clean and admitted to the error in judgment. Further, he acknowledged that this was not the first time that he had distributed explicit messages or photographs (including numerous times after his marriage). He stated that there was never a physical relationship with any of the online women. While he initially fought off calls seeking his resignation, he ultimately resigned on June 23, 2011.

Weiner's Mayoral Candidacy

After resigning from Congress, Weiner still had the itch for politics. As a result, in May 2013, he threw his hat into the ring to replace term-limited New York City Mayor Michael Bloomberg. In the beginning, Weiner was the odds-on-favorite to win the Democratic nomination over the likes of Bill de Blasio and Christine Quinn. But

then America learned about Carlos Danger. Since leaving Congress, Weiner had continued sexting relationships with three women using the alias Carlos Danger. Once the information became public, Weiner suffered immediate drops in the polls (topping out at well over a 20 point swing). In the end, Weiner's inability to control his urges cost him his political future as he finished fifth in the Democratic primary.

Even worse was the fact that his final vote count showed less than 5 percent of the Democratic electorate supporting him. This should not have been particularly surprising to Weiner, however, since there had been frequent calls for him to withdraw during the lead-up to election day in the city.

Weiner's legacy will not be for any positive political influence. Instead, he will be forever remembered for utilizing poor judgment and not correctly navigating social media when he made the photograph retrievable by individuals other than the intended recipient. The Weiner scandal has opened the doors to new questions about what constitutes sex (after all, Weiner did more than Carter's lusting in one's heart, but less than the activities of Clinton), and further questions about the blurring line between public and private life for politicians.

Other Examples

Weiner is not alone in his transgressions. State and local officials across the country have experienced similar incidents. In some cases, a misunderstanding of the technology posed the problem. In others, jilted lovers ran to the press when denied access. Examples of public officials finding themselves in trouble because of poor decision making related to sexually explicit photographs or messages include a high school principal and a student, an elected judge and his subordinate, a high school English teacher and a student, and Senator John Ensign (although in his case, sexting was not the most severe of the moral transgressions).

There are common threads that help to categorize the different types of sexting incidents. The first thread focuses on a lack of understanding of how the technology works. On Twitter, for example, there is a difference between a direct message and a tweet. Pictures sent via cell phone can be

saved and redistributed. The second thread is the arrogance held by public officials. Personalities like that of Anthony Weiner seem to be unwilling to accept that their actions could negatively affect their careers. It may be that they view themselves as made of Teflon. The third thread is an understanding of the damage that sex scandals can have on political reputations. There is an acute awareness that affairs can ruin reputations, but prior to Anthony Weiner, sexting seemed a safe alternative.

Conclusion

Given the political fallout for Anthony Weiner, there are some general guidelines that elected officials should know before choosing to partake in any form of sexting. Information placed on the Internet will be discovered. As with any other sexual activity, sexting will be viewed far more negatively if the public official is married. Sexting is viewed just as negatively as having an actual affair. It is best to not discuss or share any sexts or photographs. In terms of security, locking the phone, along with taking extra care in assuring that it never gets misplaced, is key.

Technology is beginning to catch up with sexting in a way that could protect politicians. Safe Sexting is an app by MountainDev that allows the sender to place boxes over explicit portions of photographs. However, this would not necessarily protect elected officials. It makes the action less explicit, but does not remove the underlying offense, which is most problematic within the American public. iDelete and SnapChat are two apps that permit the sender of photographs to determine how long the picture sent can be viewed. Further, iDelete actually prevents the receiver from taking a screenshot of the image on their device. Such tools could protect officials who continue to partake in sexting.

Shirky Principle, The

In an April 2010 blog post, the founding executive editor of *Wired* magazine, Kevin Kelly, coined the "Shirky principle." Kelly highlighted the following quote from media scholar Clay Shirky: "Institutions will try to preserve the problem to which they are the solution." This principle is embedded within Shirky's wider arguments related to social media and politics, which promote the potential of social media tools for positive social and political change by emphasizing the opportunities that designers can offer to users who are increasingly willing to experiment, innovate, and participate as amateurs. The Shirky principle offers explanatory power for the reaction by traditional institutions to new social media ventures, as well as a cautionary note: By refusing to acknowledge and adapt to the new social and technological dynamics of the current era, institutions risk restricting the potential for social experimentation and innovation that can be enabled through new social media tools.

The Shirky principle has many implications for the world of 21st-century politics, in which both

new and old communications and organizational structures must exist side-by-side and sometimes compete with each other. Shirky himself has applied this principle to a wide variety of "institutions," including television organizations, bus companies, and governments.

The "solutions" relate to the product or service that an institution provides and tends to be the basis upon which their existence and continued survival rests. In the case of the institutions just mentioned, solutions can include videos as a form of entertainment, transportation that aids commuting, and regulations that seek to regain social order, particularly during a time of social change. Shirky's principle draws attention to the fact that institutions end up exacerbating (or at least sustaining) the problems that they aim to solve as a result of a misunderstanding of the underlying problem or desire to defend their market share by squashing competitive institutions that have developed new solutions. While this principle can be applied to a variety of contexts and time periods, Shirky is mainly interested in technology (and social media in particular), which is reflected in the allegation that many institutions have not adapted to shifting social and technological contexts. Instead, they rely on flawed assumptions that are embedded in traditional or "old" ways of thinking and operating, and therefore they cannot even conceptualize new approaches to solving problems. Shirky believes that this inflexibility is extremely problematic and impedes the integration of technology into society.

Examples

Shirky offers the example of the British Gin Craze of the early to mid-1700s that came about in conjunction with increased industrialization and the reorganization of urban centers due to the influx of many new workers. The British Parliament sought to solve the problem of dramatic social change by focusing on the production and consumption of gin. "Gin consumption was treated as the problem to be solved, when in fact it was a reaction to the real problem—dramatic social change and the inability of older civic models to adapt." Thirty years of legislative attempts to solve the problem of gin consumption were ultimately unsuccessful, since they targeted the wrong problem and were based on assumptions that were out of touch with

changing social realities. Eventually, the integration of new social structures that accommodated the density of the population (e.g., aid societies, coffeehouses, and restaurants) helped mitigate the problems associated with this dramatic social change, and in doing so helped mitigate the underlying desires for excessive gin consumption. New ways of thinking were required in order to reimagine the problem of increased population density, to the point of conceiving of it as an opportunity.

Another example Shirky draws on is the social media response to the problem of organizing carpooling between strangers. The wider, underlying problem in this situation is commuting. Individual-based solutions (each person owning and driving a car) are not viable, and instead merely exacerbate the overall problem. Shirky argues that the key is to reconceptualize the problem. Too many cars can be seen as an opportunity if the goal is to offer an aggregate solution involving cooperation and coordination. A site like PickupPal.com offers a service that matches drivers with passengers, considering complementary routes, dates, and times while allowing users to negotiate prices and maintain privacy.

Despite this successful venture, a traditional institution—in this case, an Ontario bus company called Trentway-Wagar—stepped in, taking action that effectively sought to preserve the very same problem that it seeks to offer a solution to: commuting. Trentway-Wagar managed to have PickupPal shut down by authorities, citing an infringement of the Ontario Public Vehicles Act that related to archaic stipulations surrounding carpooling (e.g., limiting carpooling to within municipal boundaries and between home and work only). Public outcry over this decision contributed to speedy political maneuvering that resulted in changes to the act, adapting the legislation to better reflect modern social and technological contexts, allowing PickupPal to legally operate.

Conclusion

The wider context within which the Shirky principle was developed highlights the ways in which human behaviors shift over time in conjunction with the opportunities enabled by technologies. Along with these shifts, Shirky argues that society must reconfigure old assumptions about the

value of amateur production and the social motivations (connectedness/membership and sharing/generosity) that lead to social media use. Shirky privileges sharing as an important resource in the new media economy that has been increasing as a result of new opportunities facilitated by social media and shifting cultures. Yet, traditional institutions remain attached to old ways of thinking and cannot embrace new solutions, such as open source models of development, which are based on sharing and generosity.

Shirky believes that scholars are often asking the wrong questions about the role of social media, and should instead focus on how they can harness the opportunities that social media and shifting human behaviors present. However, the tension between traditional institutions and new social media remains, and traditional logic will continue to be thwarted by unexpected uses of social media. The Shirky principle aims to improve understanding of this tension.

Shot@Life Campaign

The United Nations (UN) Foundation's Shot@Life campaign educates, connects, and empowers Americans to join its cause to save the lives of children in developing countries. By expanding

access to vaccines, a child's life is saved every 20 seconds. According to its Web site, each year, 1.5 million children will die from diseases simply because they do not have access to lifesaving vaccinations. Shot@Life campaign encourages the American public, members of Congress, and civil society partners to learn about, advocate for, and donate to vaccine programs that decrease preventable childhood deaths. Through the use of new and older forms of media, Shot@Life is able to reach millions of people, encouraging their involvement in its charitable campaign. This campaign urges people to take political action in its cause, connecting advocates through Web sites, Facebook, Twitter, Flickr, Pinterest, YouTube, blogs, and e-mail.

The Shot@Life campaign builds on a 13-year global vaccination initiative started by the UN

Foundation. The UN Foundation is a leading partner in the Measles Initiative and Global Polio Eradication Initiative. The UN Foundation's Shot@Life campaign is a charitable organization, expanding on the fundamental mission of the UN. The mission of the UN is to aid in the prevention of warfare and to improve the quality of life globally. In 1998, entrepreneur and philanthropist Ted Turner created the UN Foundation as a U.S. public charity. The foundation broadens the support of the UN through advocacy and public outreach, addressing the world's problems while building public-private partnerships. The Shot@Life campaign posits that vaccines are the solution, saving more lives than any other medical intervention in the last 50 years. The Shot@Life campaign promotes the dissemination of vaccinations for the following diseases: measles, polio, pneumococcal disease, and rotavirus.

Every year, children are disabled or die from vaccine-preventable diseases such as diarrhea, measles, pneumonia, and polio. In fact, the rising death rates for children under the age of 5 are primarily the result of pneumonia and diarrhea. There is a re-emergence of polio in once polio-free areas; in addition, measles causes 450 deaths per day. The majority of the victims are young children. The Shot@Life campaign seeks to solve these health disparities globally, advocating for young children who do not have access to lifesaving vaccines. There are 10 countries that comprise 75 percent of the unvaccinated children in the world.

The Shot@Life campaign seeks to rally support through donations and volunteers. The campaign travels throughout the United States, hosting events to raise money and awareness of its cause. Individuals, small businesses, and corporations are all encouraged to become involved, whether it is through fundraising events and/or donations to the UN Foundation. Shot@Life encourages people to contact Congress, urging members to allot funding to critical foreign aid programs that promote global health and vaccines. On its Web site, people can make a donation and/or recurring gifts to the Shot@Life campaign. Furthermore, there are several ways that people can become a champion for the Shot@Life campaign, such as promoting the campaign, holding fundraisers, and writing letters to members of Congress. Shot@Life's Web site, along with other forms of

Posing for a photo at a Shot@Life event in March 2013. The campaign is successful in part from its use of social media to post photos and videos of children who have been helped by the cause and are now healthy as a result.

media, provides valuable resources to assist those who would like to advocate for its cause, such as samples of press releases, an op-ed page example, and letters to the editor.

New forms of social media provide an opportunity for the campaign to share stories of children who are in need of assistance. Additionally, there are pictures and videos posted of children who are healthy as a result of the Shot@Life campaign. The success stories shared through social media are a testament to the success of this campaign, rallying people to become advocates for its cause. Social media raise public awareness, spreading Shot@Life's campaign slogan, "A movement to protect children worldwide by providing vaccines where they are most needed." The success of this national call to action can be attributed to the number of people it can reach through several forms of social media. The Internet is a valuable tool for this campaign, providing the public with opportunities to learn how to become effective champions for the Shot@Life campaign. Social media is a valuable asset in the fight to help children globally, sharing their plight with millions of people who can make a difference.

Siri

Speech interaction and recognition interface (Siri) is a computerized personal assistant that operates by recognizing users' natural speech. Siri is a mobile communications technology application available on Apple products including the iPhone, iPad, and iPod Touch. It was first released on the iPhone 4S in its iOS 5 (Apple's fifth mobile operating system) in October 2011. Siri was created by Siri Inc., established in 2007, and subsequently purchased by Apple in 2010. Siri has a wide commercial and popular appeal, but its presumed social and cultural politics have been criticized. Dag Kittalaus, one of Siri's cocreators, stated that Siri was the name of a former coworker, and he had previously considered this name for his future daughter.

More often cited reasons for the name choice are that it is easy to spell and speak in many languages, though Apple cofounder Steve Jobs was initially unconvinced of the name's suitability. Siri, likely because of the popularity of the application, was touted as a popular baby name in 2012. Apple has never confirmed how much it paid for Siri Inc. Estimates place the figure between \$150 and \$250 million for a company that was started with an initial investment of \$24 million.

Siri's responses aim to resemble the human interaction that one might have with a live personal assistant. Siri's delivery style demonstrates an eagerness to assist the user by synthesizing extensive Web information in a personable, even witty fashion. Siri is claimed to be able to personalize itself to its user's information preferences over time. The popularity of Siri has led to similar applications such as Cluzee by Android, Jelly Bean by Google Search, and the multi-platform compatible Evi.

Criticism

Despite its user-friendly features, the American Civil Liberties Union (ACLU) criticized Siri for

failing to provide complete information on politically sensitive issues. In 2011, when the ACLU asked Siri to provide the location of local abortion clinics, Siri responded that no information was available. Other users reported that Siri responded to the same question by directing users to pro-life organizations. Journalists and technology bloggers reported that Siri was alternately able to assist users in purchasing condoms, the erectile dysfunction drug Viagra, and personal escorts, but was challenged to provide any useful information about where to find emergency contraception such as Plan B, the “morning after pill.” When asked for the location of a Planned Parenthood clinic, Siri was able to provide information.

In 2011, the ACLU started an online petition calling for Apple to fix Siri. This challenge, paired with the journalists’ and bloggers’ highlighting of Siri’s apparent shortcomings, led Apple to respond. Apple publicly denied that the cited incidents were intentional attempts to exclude or offend any of its users. When asked to endorse a political candidate or party, Siri responds by refusing to choose, demonstrating an apolitical stance. When asked about gay marriage, some users reported that Siri claimed not to understand the question. It is popular for users of both sexes to ask Siri to marry them, and Siri typically responds by instead offering friendship, or by claiming to be in love with another device. Alternate explanations for Siri’s responses point more to the technology’s ability to field general versus specific questions, and its reliance on Internet search engine-based information that may be biased, rather than to Apple’s desire to privilege any political perspective.

Siri was initially released in English, French, and German, with international versions subsequently released. New criticism arose as Siri was released in China in Mandarin and Cantonese versions, but appeared to censor all information about the Tiananmen Square protest and the date of the conflict (June 4, 1989). This apparent censorship is claimed to also apply to directions to Tiananmen Square. Previous to Apple’s introduction of Siri, search engine Google chose to leave mainland China for Hong Kong to escape government pressure to censor its information. Google’s example demonstrates China’s censorship of the Internet, which would by consequence of Siri drawing its

information from Internet sources, mean that the answers provided by the online assistant would be influenced by this restriction of information.

Language and Voice

The U.S. English Siri has a female voice, whereas the UK English Siri has a male voice. The voice actor behind Siri’s female persona has never officially been stated publicly, while former journalist and voiceover actor Jon Briggs voices the male persona. Briggs is said to have recorded the voice for a product initially named Daniel over several weeks in 2005 for a technology company named Scansoft, which merged with a company named Nuance that subsequently worked with Apple on Siri. Apple is said to have contacted Briggs and asked him not to speak publically for fear that it would shift attention away from the product and onto an individual. Similarly, Apple does not refer to Siri publicly with pronouns, but instead uses its name, and Siri does not respond to user’s requests for the application to describe what it looks like in human form, likely in part to avoid appearing racially or culturally biased.

Critics have questioned why Siri’s U.S. English voice is female, and have also posited several reasons for this choice. Some posit that female voices are more socially appealing to listeners and/or perceived to be more empathetic. Feminist criticism argues that Siri’s descriptions of itself as a humble personal assistant, deference to its users’ needs, and difficulty with answering women’s reproductive health questions are indications that Siri perpetuates stereotypes of passive femininity. Yet, it is also argued that Siri reflects how many early communications workers (e.g., telephone operators) were women in North America, and how women are often employed in the customer support field. It is argued that many of the computerized voices for devices like global positioning systems (GPS) are female in the U.S. market, and Siri follows this pre-established pattern.

Siri provides male and female sounding voices, depending on the language and region that users choose. Some consumers have the option of choosing a male voice by switching to a version of their language that supports this option. For example, English-speaking consumers can opt to use the UK English voice for Siri that presents as male. In France, like the UK, Siri is a male voice, while in

Canadian French Siri presents as female, as do the voices for Siri in Australian English and German.

Cultural critics have questioned Siri's ability to recognize accents and dialects. English language users of Siri complained that the device does not correctly recognize language spoken in specific Southern American, Scottish, Australian, and Irish accents that deviate from mainstream forms of language. Apple claims that Siri is designed to detect the accents and dialects for languages supported on its devices, though with a higher rate of accuracy for users who are native speakers of the languages in which they operate Siri. As of April 2013 Siri operates in the following regions (and languages): United States (English, Spanish), United Kingdom (English), Australia (English), France (French), Germany (German), Japan (Japanese), Canada (English, Canadian French), China (Mandarin), Hong Kong (Cantonese), Italy (Italian), Korea (Korean), Mexico (Spanish), Spain (Spanish), Switzerland (Italian, French, and German) and Taiwan (Mandarin). Users of languages not supported by Siri (e.g., Portuguese) are critical with the speed of progress or lack of progress made in this area. Additionally, critics charge that Siri was culturally biased because it initially could only provide locations and directions in the United States. This was changed in iOS 6 (Apple's sixth mobile operating system), though there were also several publicly cited instances of Siri providing faulty directions or incorrect maps.

In 2013, Apple acknowledged that the Siri and dictation applications on its devices stored users' voice data for as long as two years. Civil liberties groups argue that Apple is not adequately informing consumers about their privacy rights. Apple counters that the voice data is sent to Apple's servers in a way that leaves the user anonymous and that the data is used to improve Siri, dictation, and other voice recognition products and services. Siri's capacity to study its user's voice and preferences have led some to compare Siri to the supercomputer HAL, who turns against his human creators in Stanley Kubrick's film *2001 A Space Odyssey*. Others claim that Siri will eventually overshadow the devices and technology on which it appears.

Skype

Skype is a voice-over Internet protocol application (VoIP) that allows telephone calls, audio- and video-conferencing, instant messaging, and live voice chat, via the Internet. VoIP technology converts analog voice signals to digital signals. The digital signals are then transmitted over a computer network. The cost is significantly lower than over traditional telephone lines, but the quality of the reception is not guaranteed.

Skype has exponentially grown and represents a large part of the telephony market. It is free for those who have Skype accounts. The software can be downloaded from the Skype Web site, and can be used with desktop computers, Symbian, Android, iPhone, and the Kindle. Instant messaging is free on all devices, but text messaging costs money. To make a call to a non-Skype user, there is also a charge. Three types of payment plans exist. The first is a pay-per-minute or pay-as-you-go plan, the second is to charge the Skype

account, while the third is a monthly plan. All three plans apply globally. Also, for a fee, one can establish an online telephone number and pick up calls on Skype.

There are numerous ways of communicating with Skype. One can communicate with just the audio, which is similar to a traditional telephone conversation. One can communicate audio-visually or have a video-conference through the use of a Webcam. One can also communicate asynchronously through the use of the Skype chat function. Skype can also be used with a television screen or on a mobile phone. The same Skype services exist for businesses.

Social Media and Politics

Social media such as Skype, Facebook, and Twitter are increasingly used to create and disseminate messages to constituents. Further, constituents use the sites to discuss politics.

Along with traditional media, political candidates are using digital media to sway voters. They are using online streaming ads, interactive Web pages, YouTube channels, text messaging, chats, candidate blogs, microsites, fundraising sites, and grassroots organizing platforms as a means of reaching constituents. These forms of digital media complement, rather than replace traditional media forms, and highlight the shifting norms of campaign strategies. Skype, in particular, is a face-to-face technology that is very persuasive in advocating an argument in, for example, a conference call or Webinar with supporters. With this being the case, researchers question whether the political use of Skype and other social media sites will be helpful or harmful for the purposes of democracy.

Skype and Protests

Social media was used to organize protests in Egypt, Tunisia, and Libya during the Arab Spring in 2011. For example, Twitter, Facebook, and YouTube were used to share information about street actions. Skype was not used as much, but it was an option. Some governments censored the Internet or even cut off access completely at times, and restricted telephone use. Even though this was the case, citizens found ways to gain access to the telephone and to the Internet. In regimes where the mass media was controlled,

the Internet became a major source of alternative media.

Sleeper Effect

The *sleeper effect* is the term given to the counterintuitive phenomenon that occurs when a persuasive message with a "discounting cue" (something that would undermine the believability of the message, such as a disclaimer or a source that would commonly be perceived as having little to no credibility) is disregarded or disbelieved at first, but then over time, that message comes to grow in persuasiveness. The sleeper effect becomes even more striking when the same message from a high-credibility source loses its believability or persuasiveness over that same period of time.

This anomaly first came to the attention of researchers in 1949, and since then has been the subject of much study, debate, and fruitless efforts to reproduce. Researchers have often been able to document situations where messages from low-credibility sources became more persuasive over time, whereas the same message from

a high-credibility source lost its persuasiveness: Sleeper effects have also been produced in experimental settings within a specific framework of conditions, but there has been little success in producing a sleeper effect in actual practice. The ability to create a persuasive message that would gain in persuasiveness over time, even when delivered from an extremely unreliable source, would have usefulness in advertising or political campaigns. Thus, the efforts of cognitive and behavioral scientists since the mid-20th century to understand the operations by which a sleeper effect comes about, and to produce one at will.

Researchers have determined that a sleeper effect may be absolute or relative. With an absolute sleeper effect, the message from the low-credibility source gains in persuasiveness over time, whereas the message from the high-credibility source loses persuasiveness over the same period of time. Situations where an absolute sleeper effect can be seen to have occurred are rare; more often, relative sleeper effects are obtained. With a relative sleeper effect, the messages from both high-credibility and low-credibility sources lose persuasiveness over time, but that of the high-credibility source loses more persuasiveness than that coming from the low-credibility source.

The phenomenon was first noticed in 1949, when Yale social psychologist Carl Hovland and his colleagues were studying attitude change among World War II soldiers who were shown a U.S. Army training film, *The Battle of Britain*. In an outcome that surprised the researchers, receivers' opinion of the prowess of British soldiers was stronger nine weeks after the initial assessment of the attitudes. Hovland and his colleagues hypothesized that the "discounting cue" (that which made the source unreliable or low in credibility, or a disclaimer that undermined the credibility of the message) became detached or disassociated from the message content over time. They then reasoned that the recall of the element that was unreliable (source or disclaimer) decays over time, leaving the message content unattached to the discounting cue, and therefore able to stand alone in terms of believability.

However, repeated failures by researchers to obtain a sleeper effect over the next several decades led some to think that the findings were

either incorrect, or were simply reports of anomalies without practical application. Some scientists found the sleeper effect to be an unreliable phenomenon, and called for acceptance of the null hypothesis (that the sleeper effect doesn't exist) to "lay the sleeper effect to rest." This suggestion was countered by other researchers who believed that it did exist, and that conditions whereby it could be produced could be understood. They determined that a better course would be to try to identify the conditions and factors that would produce it.

Thomas Cook and his associates isolated four factors that must be present in order to produce a sleeper effect: the message must be persuasive, the discounting cue presented with the message must also be strong enough to counter the persuasiveness of the message, there must be sufficient time elapse between the initial test and the post-tests, and the message content must still, at the time of post-tests, carry persuasive force. There has been some support for this theory. Subsequent research has examined the sequence of discounting cue and persuasive message, strength of the persuasive message alone, hypotheses relating to "forgetting" and/or "dissociation," the context of message presentation, relationship of delayed attitude change to aspect of dual processing models such as the heuristic-systematic model and the elaboration-likelihood model, and the type of discounting cue offered.

Recent research related to the sleeper effect has found that fictional narratives affect readers' real-world beliefs. Other research focusing on the impact of negative political advertising on opinion change finds a sleeper effect produced by the general distrust of politicians by voters. Finally, related to public health campaigns that feature a myth versus fact structure, people tend to conflate myths and facts over time when presented with both in the original message. The myth actually becomes memorable as fact.

When imported to the digital environment, this suggests that social media users may remember messages and information they received via social media, but not recall the source where that information originated, which impinges on their ability to decide the level of credibility that should be assigned to it. It may well be in this contiguous area of information processing that the sleeper

effect's real significance regarding political information in the social media sphere will emerge.

Snopes.com

Snopes.com describes itself as a Web site that debunks urban legends, including "common fallacies, misinformation, old wives' tales, strange news stories, rumors, celebrity gossip, and similar items." Founded in 1995, it is owned and run by David and Barbara Mikkelsen of California; they avow no political preference or affiliation, and they do not accept funding from any outside group. There is a diverse set of advertisements that rotate through the site; some are supplied by Google's AdSense program, which displays

ads related to keywords located on pages. Snopes was the Internet nickname that David Mikkelsen chose in the Internet's early days in the late 1980s, when that was the norm. He selected it in honor of author William Faulkner's Snopes family, who weave throughout many of his works. Mikkelsen's reputation as a researcher who debunked Internet falsehoods eventually led to the domain name. As the strategic deployment of socially salient and culturally politicized "facts" via social media continues to escalate in the campaign environment, organizations such as Snopes.com are playing an increasingly important role in the governance process, especially as it relates to candidate claims about deeds done or conditions addressed in the material world.

An urban legend is a story or statement that people tell to confirm their worldview (the world is a scary place), or present a cautionary parable (beware of the government). Such legends are often related, using some type of credible authority (the story was witnessed by someone known), were local and recent, and offer details that seem possible. Examples include the tale that green cars are unlucky, an electric fan that is left running overnight can kill you with its breezes, or alligators are running amuck in sewers. Such legends have long been passed by word of mouth, but the advent of the Internet and various social media have accelerated their exposure. As a result, the Web site is a popular destination for fact checkers. According to Quantcast, in April 2013, an estimated 4,800,000 people visited the site, and an April 2013 search of Google Books noted that Barbara Mikkelsen has over 6,300 citations in others' works.

Simple ratings extend from true to unclassifiable veracity, using a color-coded bullet point. True entries are indicated by a green bullet point. These claims may be demonstrably true (meaning there is a significant amount of reliable evidence) or they may be based on some actual occurrence. A green bullet surrounded by red identifies a statement that has some truth and some error in it, or it references a claim that may once have been true, but has changed status. A yellow bullet (undetermined) is used to describe a claim that is under dispute because there is insufficient evidence to support it. For example, there may be a small piece of data that exists, but the

The "What's New" section of Snopes.com in August 2013 explored, among other stories spreading around the Internet, whether or not photos taken with smartphones would provide others with the location of images taken of children.

cause-effect relationship between that data and the claim cannot be established. A statement might be undetermined if the research cannot determine which came first: a real life incident, or the legend. False statements are highlighted by a red bullet; in this case, there is either a significant lack of evidence, the statements are implausible, or they are so imaginative that no media have reported on them. A hollow yellow bullet identifies what most think of urban legends: stories or statements that might have happened to someone somewhere and are plausible, but they are not verifiable through proof.

Web site tabs lead the viewer to sections on "What's New" (recent updates and additions) and a "randomizer" that sorts through the archives to present researched legends. The "Hot 25 Urban Legends" tab presents the top current statements widely circulating, determined by number of searches and hits, reader e-mail, and media coverage. The "Odd News" tab on "Daily Snopes" consists of links to news articles and Web sites that appear to be chosen on the basis of reader appeal. These statements are not researched. Readers can also access "FAQs" about Snopes, a glossary of some terms (such as the difference between a myth and a legend), and a message board for Snopes community conversations. Readers can also submit a rumor or a photo or videos through other

locations on the site. RSS and Twitter feeds, Facebook, and Pinterest links also appear. In this way, the constant flow of rumors and legends makes its way to Snopes.

Icons ranging from "autos" to "weddings" lead readers to pages that provide details on specific urban legends. A visit to the "food" page shows links to rumors about food contamination, cultures, odd ingredients, food origins, preparation, dining rituals, and warnings. Among the legends debunked is the "five second rule," which claims that food is germ free if one picks it up within five seconds (false), and that green potatoes are poisonous (true). In many cases, a detailed explanation of the statement and its research findings supplies the reader with source material on origins, reports of further "sightings" or versions of the statement, and media responses. The "Soapbox" icon is used for political statements that are editorial or opinion, and any research presented concerns only attribution. If a political statement asserts a fact, it is placed within the appropriate category (such as politics, legal affairs, or the military).

The site explains its research veracity with a simple and direct tone, saying that the Mikkelsons do not expect anyone to accept them as the ultimate authorities. However, all research materials they use are given in a bibliography at the end of each entry, and no entry is anonymously written. At the same time, the Web site's tone occasionally takes a turn toward the humorous or whimsy. For instance, the word "glurge" (coined by a Snopes community member) describes inspirational tales that seem uplifting, but have a darker meaning. As the Web site notes, glurge may be stories of strange things found in food, or dying children saved by prayer, and are meant to be modern parables.

Snowball Effect

In social science research, the term *snowball* is used with regard to a specific method of selection of respondents. A researcher asks a subject to identify others to whom the subject is connected, and then asks each of those identified at one step's distance from the subject for their ties to others, who are then two steps from the original subject. With each step, the size of the network increases, until all members of the community have been included in the sample. Another way of snowballing is when a researcher designs an initial sample of cases, and then collects information on all contacts of the sample members. These contacts are added to the sample, and then their contacts are discovered in the same way. By extending this process through more steps, more indirect contacts of the members of the initial sample will be discovered. Thus, there is always the question of how far to continue snowballing. According to some authors who work within the network analysis perspective, snowball sampling allows for estimating the distribution of contacts and the numbers of dyads and triads in the community, and can also be used for estimation of the size of the hidden population.

The snowball effect serves as a basic principle for social media platforms such as Facebook or LinkedIn, in which users are prompted to connect with other people depending on his or her initial connections or one-step ties. In other words, friends of friends have a higher probability of becoming friends versus individuals with no bridging actors, or those who are linked through two or more steps. The advantage for analysis of social media communities is that a researcher can see the overall size of the population (members of a group or community, visitors to a Web page, or followers of a blog) and define sample size and method of selection of respondents based on that. Thus, social media have changed the way that

people communicate and become interconnected in virtual space.

The notion of six degrees of separation, which emerged in the 1960s, says that there are six or fewer links between any two human beings on the planet, on average. With the development of social media and the growing number of users of various social media platforms, this average distance between people has been reduced. Recent research on Facebook conducted by scholars from the University of Milan in Italy looked at about 721 million active Facebook users with approximately 69 billion friendship links and discovered that, with the increasing number of users along with growing number of interconnections between them, the average distance between two registered individuals has been reduced from 5.28 immediate links in 2008 to 4.74 in 2011. This distance of almost 5 steps corresponds to 3.74 intermediaries or "degrees of separation"—as shown through Facebook, one needs about four people on average instead of five to connect to any other person in the world. This also means that if the number of users and links between them grow further, the average distance between two users will get shorter, and the snowball effect in information distribution will speed up.

The number of direct ties, as well as individual network structure, should be considered when studying snowball effects in large communities. For instance, mobilization through social media during mass public actions, such as protests or riots, would be more effective through "brokering" actors who link many smaller and densely connected groups together because a message from a broker can reach more groups in a shorter period of time, passing one or two steps from one actor to the other. In this sense, locally central actors who have numerous direct connections with those inside a group are less efficient for information distribution if they have few or no ties outside the group. However, in the case of research of less accessible communities (e.g., people with specific health problems or followers of a local music band) local leaders can be treated as gatekeepers to the other respondents in the analyzed community. In social network analysis, this approach is called respondent-driven sampling.

The snowball effect in social media is leveraged by social media marketers, public relations

managers, and public activists, especially during political campaigns. A number of studies have shown that people tend to trust direct communication over information from traditional advertising channels. The power of word of mouth can be seen in more personalized social media channels, where gossips may be perceived as trustworthy sources of information. Additionally, one can observe the snowball effect when reading the same message from different people regarding a wide range of subjects—from voting in a singing contest to fundraising activities for charity purposes, or crowdfunding.

Another important area in which the snowball effect can be crucial is civic activism and political engagement. Distributing notice of the time and place of a strike or demonstration via social media can be one of the most efficient ways to mobilize hundreds or even thousands of people. Results of elections can also be significantly influenced by social media content, such as messages distributed through blogs, forums, and social networking sites. Distribution of a provocative photo, for example, can rapidly change public perception of a candidate.

Conclusion

Social media and the snowball effect have a considerable impact on the way that people find and spread information. People and communities are now participating in social and political life and expressing their thoughts and opinions through very particular flows of information based on network structures formed in social media platforms.

Social Authority

Social authority refers to the process of using social media to build Web site authority. When comparing one site to another, social authority determines how well a site ranks among competitive search engines. In fact, the quality of the site is also determined by other search engines. Several variables contribute to building social authority, including whether the site is trustworthy, whether the content is relevant, whether the site is endorsed by other authoritative sites (the site needs to be ranked by other search engines as authoritative, Google.com in particular), how long the domain has existed, length of visit (how long visitors spend on the site, which is dependent upon whether the visitor's needs are met or not), page visit (the number of pages viewed during a visit, indicating the degree of interest and popularity of a Web site), and bounce rate (when a visitor exits the site immediately upon entering).

These variables are determined by conducting a Web site analysis. Google Analytics is commonly used to analyze the behavior of visitors while on a Web site. Noting the trends of visitors is important in planning the overall design of a site. In general, Google determines the authority of a site through page rank. Page rank is assigning a numerical rating to an entire document, or elements within a document, technically referred to as link analysis algorithms. If readers consistently conduct searches on the pages, this action can establish the site as relevant. Fresh content introduced every few months will keep the site relevant. Within three to six months, one has created a Web site that ranks thousands of terms. As visitors type in the keywords associated with the Web site's topics, traffic will be driven to the site based on those keywords. A rise in search

engine rankings will result. With an authoritative site, the specific mention of a keyword can propel the site into the top-10 ranking. If visitors to the Web site perceive the content as relevant, then any word on the site can become a keyword.

If the page ranks among the top 10, search engine algorithms pay attention to the number of clicks received on the page, as well as the number of visitors who have used the keywords. An attention-getting title helps elevate a page into the top 10. Site authority can be built using specific keywords. One can perform a keyword search, obtain a series of competitive keywords that the site could target, and supplement the content with back links to elevate the site's relevance among search engines. One can write articles and posts about the keywords, and start the articles with a specific focus. Each title could incorporate a keyword, and the key word can be placed strategically in the beginning, middle, and end of the article, with links to an authoritative site and links to those links.

The page will rise among search engines as a result of Google's search algorithm. Social media listening monitors aggregate data from the Internet to determine the traits of a population, including age, income, employment status, educational level, and homeownership data. Such information helps to define the target market. Social media listening research determines how much the site is discussed compared to that of the competitor's, whether that talk is positive or negative, and gives the business a chance to counteract negative talk. Also, social media listening monitors the Internet for hotly debated topics. A topic generating much discussion can be the impetus for developing a new initiative.

Twitter and Facebook

Concurrently, social media listening plays a role in evaluating efforts to market a product and determining which efforts are the most productive. Forums, blogs, portals, discussion boards, and social sites will cater to a certain demographic market; they can be used to refine a target market. Facebook and Twitter can be incorporated into the search engine results; currently, this method is used by the Bing search engine. The results of a search show clickable items from Facebook and Twitter. In fact, Twitter and Facebook can also be

used to develop the first tier of links to a site. Linking to high-ranking media sites can increase traffic to the Web site. Social media incorporates a means of starting or continuing a conversation with the general public by using social media channels. In a sense, it is listening to what is said on social media channels and responding to the sentiment.

In order for media to be social, the bulk of the content must be online, should allow users to communicate without fear of reprisal, and should allow for an exchange of dialogue between user and sender. Forms of social media include social networks sites such as: Facebook, Twitter, YouTube LinkedIn, online communities and discussion groups, wiki's, forums, books, really simple syndication (RSS) feeds, blogs, and microblogs. It is not necessary to utilize all of the forms of social media, but use depends upon one's social media goals. Demographics show that Twitter users tend to be between the ages of 25 and 44, with a sharp decline in users over 55 years of age. Users from 12 to 17 years of age use the site primarily for social networking and microblogging.

Depending on which segment of the market they are trying to reach, companies can use the microblogging tool to their advantage. Further, because of its retweeting capability, Twitter is a social networking powerhouse. Retweets can cause a subject to go viral in a short length of time. Retweets occur when an original message is sent to friends, who in turn send the message to their friends. Users often use a tweet to pass along a link to an article or a Web site.

Companies can strategically plan how to use the retweeting and linking capabilities of the site. Also, because of the sheer number of tweets amassed on a daily basis, raw data from the tweets are often used by sociologists to inform their opinions about the public's use of a brand and to gauge the mood of community during a popular event. Companies can actively use tweets to gather raw data about the public's perception of their product, and during a major event to sensor the public's reaction to it.

In addition to Twitter, Facebook is a popular social networking site. For online marketing, it has become an indispensable tool. A specific advantage of Facebook is that when marketing a product, one can choose a target audience based on demographic data. Another feature of

Facebook is that it incorporates an e-mail messaging feature on the site, which if strategically planned, could be used to a business' advantage. Instead of a traditional advertising campaign, one could facilitate an advertising campaign on Facebook, thereby capitalizing on the popularity of the site. Such a strategy would generate more traffic and build relationships.

In summary, social authority is determined by a number of factors, including analyzing the trends of visitors, developing useful content, initiating quality links, and receiving exposure on social media sites like Twitter and Facebook. Political Web sites also gain social authority through sites such as YouTube, Twitter, LinkedIn, and Facebook. These sites allow campaigns at the district, state, and municipal levels to create interactive candidate Web pages; write blogs about candidates; write the candidate's biography; disseminate information through e-mails, text messaging, and blogs; create a YouTube channel; establish Twitter accounts for each public; establish Twitter feeds; establish RSS feeds; advertise online; create Facebook pages; write on Facebook walls; establish campaign microsites; and establish a candidate Web page.

Further, Facebook allows users to post content such as videos, links to campaign Web sites, and news stories. Facebook becomes particularly valuable in targeting a demographic market. In fact, a demographic market can be targeted based on data gathered from Facebook profiles. Utilizing Facebook, in general, affects how messages are created, received, and circulated. Social media sites have changed the norms for targeting demographic markets, campaign messaging, and fundraising, making campaigns more efficient when paired with traditional media.

Social Bookmarking

Social bookmarking is the access to resources found online. One can manage, organize, store, and search for online resources. Resources include Web sites, news, videos, music, recipes, and photographs. These resources can be transferred online via the Internet, blogs, and social networking Web sites. Instead of bookmarking the sites to one's PC, the sites are saved to an online account. This is the difference between "social bookmarking" and "bookmarking" a site. Because resources are shared, the data can also be accessed and used by commercial and political organizations. Many voters use social media and bookmarking sites to become engaged with the political process. Organizations can use this data to find groups with similar interests. Once this information is gathered, it can be used to profile groups that are prone to conservatism, liberalism, or against the political candidate, within a defined geographic area. Moreover, from the data, one might determine possible donors, volunteers, or others that might want to be involved in the campaign.

Tagging is characteristic of social bookmarking. It allows users to develop their categories and to share vocabularies with others, who in turn start using and changing the same vocabulary. This process has been extended to multimedia files and e-mail. These shared vocabularies are known as "folksonomies." Folksonomy and tag networks are used by political organizations to find voters with similar interests. The tags can be organized into a graph that shows the semantic correlation between tags with different forms. Based on the tags, one is able to determine voters who may have similar views. The campaign message can be targeted to these voters online. The Delicious bookmarking Web site was founded in 2003 and originated the terms *tagging* and *social bookmarking*. Tagging is a term for labeling

bookmarks. On the Delicious Web site, one can search, store, and peruse online sites. Further, these sites may be made public to others. Delicious is also considered a social news site. Social news sites collect the most talked about news stories from across the Internet. They are useful to magazine publishers, journalists, and bloggers.

Other social news Web sites include Digg, Reddit, and Stumbled Upon. Digg publishes the latest news stories abounding on the Internet. Stories can be directly read from the company's site by subscribing to a daily e-mail or downloading the iPhone app. Subscribers may also submit a link. Similarly, with the Reddit site, the content is user generated. Users vote as to which stories are prominent, and which ones fade to the background. Subscribers are allowed to form online communities, called "subreddits." The groups are moderated by volunteers. Comments can be posted on any of the news stories. Finally, Stumbled Upon is a collection of sites submitted by users. The categories include humor, special deals, best places to shop, and games. Relevant sites can be saved online and sent to a network of people. Further, the sites are saved in one location, granting everyone in the network access to the sites. One can browse through the sites based on the most popular, those that have been recently added, the sites that belong to a specific category, and the sites that other people have bookmarked by typing in a keyword. One can also look at what other people have tagged. Social bookmarking may be used to facilitate domestic political campaigns and to organize protests. Organizers usually open an account online with Delicious.

Although social bookmarking is phenomenal in the sense that taxonomies are user generated, several criticisms of social bookmarking have emerged. One includes the problem of varied user differences. A heterogeneous population contributes to tagging, folksonomies, and social bookmarking systems, so the purpose and quality of social bookmarking systems vary. The question becomes: How does one achieve a quality social bookmarking system that is homogenous? A second problem includes the fact that the tags are not coordinated with other users, resulting in an aggregate number of tags applied by different users. Researchers are not sure whether such a

system provides overarching meaning or not. A third problem occurs with the fact that the current tags may not represent the interests of users that have changed. A fourth problem exists with the fact that the use of tags and folksonomies has exploded. How does one leverage a system that continues to grow and expand? Along these lines, a number of research efforts have ensued to improve tag-based clustering and browsing of Web-based content.

Social Capital

With the proliferation of social networking sites such as Facebook, Twitter, and Google+, social media have become the dominant Internet services around the world. The increasing popularity of social media has spawned numerous studies on the social and political impact of social media use. One major domain of research is on the role of social media in social capital and civic engagement.

Social capital is an interdisciplinary concept that can be broadly defined as individuals' connections to others in their community and social

networks. More representative conceptions of social capital are provided by sociologist James Coleman and popularized by political scientist Robert Putnam. Coleman considers social capital to be social resources existing in multiple dimensions of a social structure to facilitate social action to produce various benefits. It includes social relations of all sorts, such as networks, obligations and expectations, and norms and sanctions. Building on Coleman's work, Putnam has a narrower focus in his notion of social capital. His conception emphasizes specific dimensions of social interactions that are crucial for the well-being of democratic governance, such as norms of generalized reciprocity, trust for mutual collective benefit, and voluntary group memberships and networks of civic engagement. In summary, social capital may be understood and defined in terms of (1) norms and values, (2) social networks, and/or (3) consequences—voluntarily produced collective facilities and resources, civic engagement, and/or political participation.

Social capital, given its focus on relationships, can also be categorized based on the strength of ties and social structures. This understanding of social capital distinguishes between various conceptions of social capital based on the types of relationships they represent. For example, the terms *bridging social capital* and *bonding social capital* are used to describe different forms of relationships. Bridging social capital reflects connections that are mostly weak ties or casual acquaintances. It is best suited for the distribution of novel information from heterogeneous networks. Bonding social capital, on the other hand, represents the strong ties one has with family and close friends. It is best suited for creating group solidarity among connected others and providing social and emotional support.

More recently, scholars also differentiated between offline social capital and online—or sociotechnical—capital. For example, the concept of sociotechnical capital has been proposed as a component of social capital that emphasizes how social and technological affordances of the Internet affect people's ability to work together.

Social Media and Social Capital

Scholars have actively examined social media's impact on social and political life. One principal

area of research is the role of social media in generating and maintaining social capital. Some overarching questions include the following: First, what are the possible effects of social media use on social capital processes? Are social media enhancing or decreasing social capital? Second, are users using social media primarily to reinforce their existing offline relationships in social media, or are they using them to interact with strangers?

Social media, especially social network sites such as Facebook, provide special affordances to facilitate user interactions and articulate their social networks. The ability to maintain social connections via social media is inherently related to social capital because individuals seek to both maintain and expand their social networks through their use. Therefore, scholars typically propose positive effects of social media in social capital, and empirical studies generally find such positive effects. For example, researchers have focused on the influence of Facebook use on social capital among college students. This is not surprising because social media, especially Facebook, is the most popular social networking site (SNS) among undergraduate students in the United States.

It is argued that social capital is important to college students because they are often removed from their old social networks when they enter college. Therefore, the third form of social capital, maintained social capital, refers to one's ability to stay linked to old social networks that one is no longer physically connected to. College students' use of Facebook has been found to be positively associated with the formation and maintenance of all three types of social capital: bridging, bonding, and maintained social capital. The strongest relationship was found to exist between Facebook use and bridging social capital. Additionally, there is also evidence that Facebook usage can provide the greatest social capital gains for users with low self-esteem. These results were replicated in subsequent investigations of the relationship between social capital and Facebook use.

Extant research has also looked at the social capital outcomes that result from specific uses of Facebook. That is, how Facebook is used to connect with other people by its users. It was found that individuals who used the site to learn more

about people with whom they have some offline connection have enhanced social capital. However, those who use Facebook to connect with strangers or close friends did not have the same effect. Similar investigations have examined relationships between Facebook use among college students and various aspects of social capital. The intensity of Facebook use has been found to be positively associated with life satisfaction, interpersonal trust, and civic participation, but not political participation. The use of “Facebook Groups,” which are user groups based on common interests, has been found to be positively associated with both civic participation and political participation. These findings suggest that using certain features of social media may enhance feature-specific participation.

The majority of studies in social media and social capital to date tend to use undergraduate student samples. However, research using a general population sample has found similar connections between civic participation and social media use. For example, an investigation of citizens’ political and civic participation during the 2008 presidential campaign found that reliance on social media use was related to increased civic participation, but not political participation. This suggests that social media users are oriented toward maintaining social relationships with their friends, which may be a catalyst for community and civic engagement. Similar research using a U.S. national sample has found that using social media for information purposes generated more social capital and boosted both political and civic participation.

International Research

The relationship between online social capital and political participation has also been investigated outside of the United States. For example, research on the relationship between online social capital and online and offline political participation has been explored in Singapore. Results found significant relationships between online bridging social capital and online political participation and between online bonding social capital and offline political participation. The findings seem to suggest that online bridging social capital plays a crucial role in mobilizing Singaporeans in an online setting and that online bonding social capital is vital to reviving offline political

participation by boosting strong ties that already exist in an offline setting. These findings provide some indications of the potential of social media use in similar countries that have significant constraints on offline political expression and where traditional settings for political and civic participation are quite limited.

Another major question revolves around the extent to which users utilize social media to connect with their close friends, latent ties, and strangers. Research studies indicate that social media are primarily used to seek additional information about people with whom users have some offline connection. This means that users are not likely to use social media to maintain existing ties with close friends or to initiate connections or friendships with strangers. As such, there may be great potential for individuals to enhance their social capital by using social media to convert weak ties into strong ties.

There is great potential for social media in the democratic process. However, the potential depends on whether people use social media for information and relationship-building purposes. If so, social media use strengthens social capital and enhances political and civic participation.

Social Computing and Social Information Processing

Social computing is one of the most widespread trends of the last decade. From friendships and families to politics and presidencies, new communication technologies are embraced by individuals and organizations alike in order to develop,

nurture, and sustain social capital. Concomitant with the prominence of new technology in the social realm is the prominence of research on the processes and practices inherent to social computing. There is a growing body of research that helps build a bridge of understanding between the communicative processes that exist in people’s personal lives and their political worlds.

Social Computing

Cyberspace has become a widely utilized milieu for social interaction. An ever-increasing number of technologies (e.g., applications, services, and products) facilitate social interaction and collective action on the Internet and beyond. Blogs, e-mail, wikis, instant messaging, peer-to-peer networks, social networking sites (SNSs), and open source communities, among others, are commonly referred to by researchers as agents of social computing. Whether taking part in a single online community or living a multifaceted life on Web 2.0, research indicates that increasingly people are turning to social computing to meet their individual or collective needs.

What undoubtedly makes social computing attractive to so many is the interaction and collaboration among users. Research indicates that people not only use online social spaces to develop and maintain relationships as well as

Environments like Facebook, LinkedIn, and Twitter may be “channel lean” in that they cannot provide nonverbal social cues, but they can be a quick source of social information that one would not likely obtain during a brief face-to-face exchange.

enact relational routines, but also to disseminate information, share expertise, and build collective identities and power. Studies indicate that many individuals utilize instant messaging and SNSs to engage in “everyday talk,” and that these simple interactions create a sense of belonging to the world, and often lead to a deep sense of interconnectedness to others.

Research in the field of social support also reveals that peer-to-peer networks often allow a heterogeneous group of users to come together for a homogeneous purpose. That is, a wide variety of people can assimilate to pursue a common goal such as facilitating a learning group, taking part in a medical support group, or forming a political action committee. Whether using a blog to share information with friends or a wiki to share expertise with strangers, social computing continues to challenge the ways that social ties are created and managed. Moreover, the processes through which people communicate in these online environments continue to evolve.

As new social computing technologies continue to emerge, it is not only where people communicate online, but also how people communicate online that is subject to change. According to Joseph Walther’s social information processing theory, people are motivated to manage interpersonal impressions and affinity, regardless of the medium through which they communicate. He argues that various computer-mediated environments spur users to adapt the encoding and decoding of social information (e.g., socioemotional or relational content) of messages in order to manage impressions. Face-to-face interactions, for example, are channel-rich environments that typically contain language, facial expressions, eye contact, and tone, among other social cues, in a typical exchange. Social computing environments, however, are often channel lean, restricting the means through which common nonverbal social cues (e.g., facial expressions, eye contact, and tone) are used to communicate.

Social information processing theory poses that people adapt to mediated environments such that the content of the exchange often serves as a substitute for the cues that may be restricted by the social computing platform. Though many people have interpreted this to mean that users simply utilize emoticons (such as ☺) or acronyms

(such as LOL) to express emotions in channel-lean environments, Walther’s theory instead forwards that users enact complex, yet often subtle, shifts in their language content and communication style in order to convey social information that may have otherwise been restricted by the environment. In short, social information processing theory suggests that a change in where we communicate prompts an evolution in how we communicate. Walther also argues that there is a temporal difference between channel-rich and channel-lean environments, such that a decrease in the amount of social cues present in the communication environment leads to an increase in the amount of time it takes to convey social information and manage impressions. Quite simply, the fewer channels available to communicate the longer it may take to develop and/or manage relationships.

Though the propositions forwarded by social information processing theory have received and continue to receive a great deal of support in the empirical literature, researchers have begun to question the utility of the theory since social computing has become increasingly sophisticated and channel rich. For example, there are many instances when traditionally channel lean environments like Web sites (e.g., Facebook, LinkedIn, and Twitter) may provide a great deal of social information about people in a short amount of time that one is not likely to obtain in a brief face-to-face exchange.

In addition, some social computing environments allow for synchronous (e.g., Skype, instant messaging) communication wherein users can engage in simultaneous communication in real time and, in turn, speed up the exchange of social information. While theorists have questioned the utility of social information processing theory, a great deal of empirical evidence remains in support of its fundamental tenets. Moreover, the tenets of social information processing theory have the capability of informing those interested in effective relationship development and maintenance across a wide variety of contexts, including politics.

Social Computing Practices in Politics

New technologies are undoubtedly altering how people interact in their social lives and are playing

an increasingly significant role in political worlds. Just as social computing has been used to develop and/or maintain close personal relationships for millions of individuals, it is used by political candidates to build relationships with constituents. From “personal” e-mail and text alerts from candidates to live chats and social network feeds, political candidates are finding new and inventive ways to harness social computing to help voters feel connected to their campaigns and, moreover, motivate voters to feel connected to candidates as individuals.

Nicholas Christakis and James Fowler, authors of *Connected*, note that President Barack Obama “forever changed the face of politics through the use of new technology” in his 2008 presidential campaign. The Web site mybarackobama.com, built by one of Facebook’s founders, Chris Hughes, logged over 1.5 million user accounts at its peak. Interestingly, many users were not logging on to this Web site to simply gather information about then candidate Obama. Instead, they were logging on to engage in social interaction and to take part in political action.

Through an online social presence, President Obama was not only able to connect with individual voters, but he was also able to connect voters with each other. Reports vary, but it has been estimated that mybarackobama.com facilitated between 100,000 and 200,000 campaign-related events and served as an organizing tool for over 25,000 community-based political support groups. What’s more, these reports do not include the number of events and support groups that were organized outside the purview of the official campaign Web site. It is clear that the Obama campaign’s social networking efforts not only influenced the outcome of the 2008 election, but it appears that these efforts have shaped the way that many Americans continue to engage in our political process.

The Pew Research Center for the People and the Press report that 56 percent of Americans watched the first live presidential debate of 2012 and 11 percent of Americans “dual screened” the live debate, meaning that they watched the debate on television while concomitantly following dialog or commentary about the debate in real time online. What’s more, 5 percent of dual screeners actively engaged in posting comments about

the debate in an online social network. And once the debate concluded, 36 percent of Americans reported gathering information about the debate from an online social network. One thing is clear from these figures—social computing is playing a significant role in the American political process and it appears to be here to stay.

Emerging Areas of Study

Social computing is a rapidly evolving field that has garnered the attention of researchers and practitioners alike. People are developing and managing relationships face-to-face, over the phone, via text message, on e-mail, in social networks, and in online support groups, among other means. Political relationships are no exception to these trends. As new technologies continue to emerge, so do trends in social computing research. For example, scholars interested in social relationships and new technologies continue to examine how people manage multimodal identities, as well as how these multimodal identities impact their sense of individual and relational well-being. Relationship scholars also seem increasingly interested in issues of online disclosure, influence, social support, social networks, and privacy. Likewise, those interested in attitude and behavior reinforcement or change among voters are pursuing similar topics from an applied political standpoint. From scholars interested in interpersonal relationships to those interested in political relations, many opportunities for exploration across these fields of study remain.

Social Good Summit

The Social Good Summit of 2011 took place in September during United Nations (UN) week. The goal of the event was to convene a dynamic group of leaders, including technophiles, innovators, entrepreneurs, social media gurus, bloggers, and all others who wanted to contribute and work in the social good space, either live or via Internet. The point was to raise awareness about challenges that impact the world and generate a conversation about innovative solutions to these challenges in the context of the UN General Assembly Week in the hopes that those in power would address these new challenges.

The byproduct of the connection of all of these minds would be the ongoing collaboration and open trade of best practices for social good. This ongoing, sustainable forum of intellectual leadership would be poised to generate more innovation and solutions for global challenges.

Agenda

Monday, September 19, 2011, featured a session called "Next Generation Leadership: An Opening Keynote Conversation" given by Ted Turner, chairman of Turner Enterprises Inc. and Adam Ostrow of the UN Foundation and editor in chief of Mashable. Alec Ross, Secretary of State Hillary Clinton's Senior Advisor for Innovation,

presented "How Networks Are Changing Global Foreign Policy and Activism." Next, discussing "The Future of Maternal Health," were Christy Turlington Burns of Every Mother Counts (EMC) and Heather Armstrong, creator of dooce.com and advisor of technology and media for EMC. Howard G. Buffett, executive director of his foundation, spoke about "Social Value Investing: A New Paradigm for Future Generations." Finally, author Simon Mainwaring presented "Building a Private Sector Pillar of Global Social Change."

The second day of the summit opened with a joint presentation on "Ancient Values and New Media: The Future of Ethics in a Connected World," given by Pete Cashmore of Mashable and Nobel Peace Prize winner Elie Wiesel of the Elie Wiesel Foundation for Humanity. Next up were Lance Armstrong and Doug Ulman of LIVESTRONG, discussing "The Original Social Network." Then a panel discussion moderated by Aaron Sherinian, vice president of communications and public relations for the UN Foundation, on the following topic was presented: "Women and Girls Lead: Where Storytelling, Gaming and Public Media Converge." The panel was comprised of actor Geena Davis; Abigail Disney, of *Women, War, War & Peace* renown; Tamara Gould, vice president of ITVS International; and Asi Burak, copresident of Games of Change.

The summit's third day started with a joint discussion titled "How Micro-Financing Is Enabling Social Change," featuring Dr. Muhammad Yunus of Grameen Bank and Matthew Bishop, the American business editor and New York bureau chief of *The Economist*. The CEO of the UN Foundation, Kathy Calvin, next presented "A Conversation with Global Leaders on the Importance of Social Good." Next, Skype CEO Tony Bates presented on "The Future of Technology and Education: Skype in the Classroom." The U.S. Agency for International Development (USAID) Administrator Raj Shah then discussed "Developing Technology for the Developing World: The Big Challenges." Finally, experts on vaccinations in childhood convened with a large panel. The last day featured an event showcasing various start-ups that address social issues with innovation, technologies, and Internet use. The showcase was also a competition for a \$10,000 cash prize.

Impact

More than 1,600 new media notables and innovators registered for the in-person event, including three Nobel Prize laureates, world leaders, activists, U.S. government officials, movie stars, business leaders, bloggers, and journalists. Organizers estimate that more than 100,000 have watched the live stream of the summit proceedings to date, totaling more than 1 million hours of footage watched. Innovators from five continents participated in the summit, which was also live-tweeted.

Social Issues Advocacy, Netroots Driven

Netroots is a diverse and decentralized network of progressive bloggers that officially emerged in 2005. The goal of these activists is to expand the influence of online progressives on the national

political and social stage and to support candidates who advance a progressive social agenda. Many of the original members were vocal dissenters and online leaders of the opposition to the George W. Bush administration. Their agenda has persistent themes, but the flexibility of the Netroots community means that they are ready to quickly marshal forces to speak out on any number of issues that arise in the public discourse, spurred by political battles or national/international events. The view of these activists is that online activism can be an effective and important tool of political influence when properly mobilized.

Through petitions, actions such as boycotts and strikes, campaigns, and events such as the annual Netroots Nation convention, netroots activists use a variety of strategies and platforms to organize and deploy their social media capital. The netroots network has grown to encompass a number of traditional Democratic constituencies, but their discourse on social issues is predominantly focused on equality for women and lesbian, gay, bisexual, and transsexual (LGBT) communities, as well as economic and justice issues insofar as they relate to issues of discrimination based on race, gender, or sexual orientation. Although they are diverse, and tend to see connections between issues, the social issues that have activated the Netroots during recent political campaigns mainly revolve around LGBT and women's reproductive rights.

For progressives, social issues overlap with economic issues and even broader policy issues such as immigration. The issue of health care and women's rights overlapped as politicians, pundits and organizations came into conflict over provisions in the Affordable Care Act that compelled insurance companies and employers to cover birth control. The issue of income inequality is frequently invoked in order to mobilize multiple constituencies, as it was during Occupy Wall Street protests in fall 2011. Arguments about social welfare and health care programs often stress questions of personal responsibility. Terms such as "lifestyle choices" and "entitlement society" bring the personal lives of citizens into the realm of the economic. In response, the Netroots have employed strategies such as economic sanctions against corporations and organizations to make a point about a social issue.

Mitt Romney's choice of words during a presidential debate, referring to a time during his tenure as governor when his aides brought him "binders full of women" as possible additions to his administration sparked a frenzy on social media sites.

The Netroots activists are dedicated to harnessing the power of the Internet as a tool of action, rather than just viewing it as a method for mobilizing traditional offline political activities such as voting. The network is diffuse and diverse enough to penetrate every social media platform. Connections are loose, and Netroots activists rely on viral transmission of local and regional stories that speak to their agenda and goals.

Politicians and Political Campaigns

The early days of Netroots activism are associated with the presidential campaign of Howard Dean in 2004, and Netroots activists have since mobilized their network for online political campaigning in every subsequent election, gaining in reach and penetration as social media has taken hold in popular culture. Donations are mobilized for local and statewide candidates when a candidate is seen as congruent with the Netroots agenda on social issues.

During the 2012 elections, the issue of restrictions on abortion in the case of rape inspired Republican candidate Todd Akin to use the term *legitimate rape*, asserting that if a rape was legitimate, pregnancy would not occur because the female body had ways to "shut that whole thing down." This was an example of a politician making a comment that quickly became an Internet

meme, spread throughout social media networks. The meme of the Republican War on Women, as evidenced by such statements, was used successfully in fundraising efforts for candidates across the country.

Presidential candidate Mitt Romney was the source of several memes during the 2012 campaign, and one that particularly ignited the Netroots was his comment that during his tenure as governor, when there was a suggestion that his administration did not include enough women, his aides brought him "binders full of women." Viewers who were live-tweeting the debate immediately seized upon this comment. Online and traditional media converged and sustained endless jokes about "binders" and "women," and Governor Romney's awkward syntax. These memes provided late night comedians and political pundits with content, and perhaps more importantly, a scrolling exhibition of public sentiment, expressed in memorable ways that often draw connections between multiple issues.

When it comes to fundraising, the memes that reinforce key campaign messages can be employed to motivate voters who have money to donate and wish to support candidates, or perhaps just as often, to oppose candidates whose views are seen as impeding progress. Sites such as ActBlue.com highlight candidates based on their positions on social issues that are important to progressives.

Petitions

Progressive activists employ numerous petition sites, and petitions are circulated through social media platforms. Sites that allow for the creation and distribution of online petitions include Change.org and Care2Cause.org. One example of a highly successful petition was created by the mother of Trayvon Martin, a young man who was shot and killed in Florida when he was on his way home from a convenience store in his father's gated community in Sanford, Florida. The petition had more than two million signatures, and was still attracting new signers more than a year after it was launched.

In the Trayvon Martin case, social media played a major role in pressuring authorities to bring charges. For activists, the case was a confluence of issues, but the primary issue was race and

how it influenced both the actions of the shooter and the decision not to press charges against George Zimmerman, who admitted to the killing. This decision was only reversed after intense social media pressure. In this case, large numbers of signatories to a petition provided activists with evidence, and kept an issue on the public agenda. The White House also accepts petitions on its official Web site, providing responses to petitions that achieve a preset level of support. In the world of online political discourse, petitions allow for online activists to bring attention to issues they wish to influence.

Boycotts

Another strategy employed by Netroots activists is the boycott, which involves the avoidance of certain corporate brands or retail outlets. Also utilized is the opposite strategy called a “buycott,” in which supporters of a particular issue or principle will intentionally purchase products made by companies that have demonstrated sympathy for that issue. Boycotts and buycotts may be launched for a variety of reasons, but social issues have proven an active site for this type of protest in the past decade. When the CEO of Chik-fil-A fast food restaurants made statements opposing same-sex marriage, online activists organized a boycott on behalf of LGBT rights, while activists on the right organized a Chik-fil-A Appreciation Day led by former Arkansas governor and presidential candidate Mike Huckabee.

Social media also provide platforms that allow Netroots activists to crowdsource and actively aggregate information about companies and businesses that support a progressive agenda, and those who are seen as perpetuating inequalities or exploiting the ideals of the movement. One example was the reaction to the Unilever Corporation when it released a commercial for its Dove brand of products, aligning the brand with the resistance to improbable and idealized notions of female beauty in advertising. This ad was considered compelling, and spread virally on social networks, especially Facebook. However, online activists were quick to respond with a debunking critique, pointing out that Unilever was also the parent company for the brand Axe, aimed at young men and infamous for commercials filled with images that are misogynistic.

Conservative voices have dominated the realm of talk radio at the national level for some time, particularly Rush Limbaugh and his three-hour daily radio program. Through this widely syndicated vehicle, Limbaugh has exerted great influence over the thinking of conservative activists and politicians. However, on February 23, 2012, a Georgetown University law student named Sandra Fluke testified before a congressional committee on the issue of birth control accessibility, speaking against “morality clauses” that would allow employers to deny birth control coverage to students and staff based on the argument that it offended their religious beliefs. Conservative bloggers criticized Fluke with headlines about “Sex-crazed co-eds.” On February 29, Limbaugh delivered a monologue about Fluke on his show, calling her a “slut” and a “prostitute” who wanted “taxpayer subsidized sex.”

The response to Limbaugh was swift and negative. By March 3, he had apologized, but by then a campaign had been initiated by the Netroots that came to be known as Stop Rush or Flush Rush. Netroots activists decided to go after Limbaugh’s advertisers, national and local, and because of the widespread and extremely negative publicity Limbaugh received, this campaign resulted in the exodus of a number of Limbaugh’s sponsors. One year after his comments about Fluke, netroots activists at StopRush.net are still promoting the boycott, and have introduced a mobile phone application so that citizens can avoid Limbaugh advertisers. Through a loose association of hashtags, and/or membership in Facebook groups, Limbaugh critics collectively monitor, document, and publicize the names of advertisers who are heard on his program. On the one-year anniversary of the campaign, activists claimed that Limbaugh had lost 2,600 advertisers nationwide. In May 2013, a CNN article asked “Is Rush Limbaugh Still Relevant?” In this article, Cumulus Radio CEO Lew Dickey was quoted as attributing a steep decline in 2012 sales to the success of the boycott against Limbaugh.

StopRush.net is the work of a number of activists, and represents a crowdsourced approach to technology, information, and free market persuasion. The @StopRush Twitter account is operated by an employee of Media Matters for America, a media watchdog organization, although the

account profile states the connection and indicates that the posts represent only the individual. While this account is active and focused solely on Limbaugh, the StopRush network benefits from numerous less-dedicated, but interested participants who help to monitor and spread the names of Limbaugh advertisers through sharing on social media sites.

Events

The Netroots Nation convention began in 2006, and has been held annually in various major U.S. cities since then. The DailyKos Web site is a major hub for many Netroots activists, and the Netroots Nation emerged from their YearlyKos event. The convention brings together online progressives from across the country, where they conduct panels and workshops designed to train individuals to be more effective online and offline activists. This event has grown, and the increasing influence of the Netroots activists is demonstrated by the increase in participation by numerous media and political elites, and the harvesting of talent from the Netroots to more traditional political campaigns and nonprofit organizations. The convention has become a major event for progressive activists, and offers journalists and bloggers the chance to connect online identities with “real life” people who have a variety of offline roles.

Loose Affiliations/Decentralized Organization

Twitter users found via a search for “Netroots” editors of major progressive Web sites such as RawStory and DailyKos. There are leaders among the activists such as DailyKos founder Markos Moulitsas and John Aravosis of AmericaBlog, who are viewed as founding figures. There are also celebrities who lend their images and enthusiasm to the causes, most notably George Takei, an actor who starred in the original *Star Trek* television series. He is now a prominent Facebook poster, sharing memes, many of them related to social issues, and in particular marriage equality. His Facebook page has more than four million “likes,” and his popularity is a testament to the viral nature of comic presentations in social media because the vast majority of the content he shares is humorous in tone.

While sites such as DailyKos and Democratic Underground.com serve as hubs for Netroots activists, the network is large and dispersed across a wide variety of sites representing causes, organizations, communities, and interest groups. Sites such as Facebook and Twitter serve as staging grounds and fuses that can ignite a meme and rapidly spread it around the country, and in some cases, the world. A good example of this type of activism is provided by the marriage equality battle. As the Supreme Court heard arguments in two marriage equality cases during the last week of March 2013, more than 2 million Facebook users (and many Twitter users) changed their profile images to a red background with an equal sign, symbolizing their support for marriage equality. Many personalized variations also appeared, including one in which two strips of bacon symbolized an equal sign. The phenomenon was widespread enough to catch the attention of many traditional print and broadcast news outlets, and generated stories about the public show of support. Although the image began with the human rights campaign, by the time it spread through the social media network, many users were far more familiar with the meaning than with the origins of the image.

Many of the Netroots projects and tactics were not considered serious when they first emerged, but the now well-established network of activists has proven that the groundwork that was laid in the early days of online politics has paid off. Much like the Occupy Wall Street movement, supported by many in the Netroots community, the network is simultaneously local, national, and international, without clear boundaries on membership or sharply defined roles and hierarchies. It is an experiment in an alternative media model, uniquely suited to the affordances of the Internet. Activists organize themselves, moving with agility to respond to issues and outrages, and are harnessing the power of online fundraising and information crowdsourcing to an unprecedented degree. Connecting local stories to national issues and vice versa, and monitoring public discourse across mediums and ideologies, Netroots activists are answering the power of industry lobbies, traditional media outlets, conservative think tanks, and political action committees with online mobilization and the exercise of consumer pressure

through boycotts organized and sustained by the netroots. Particularly on social issues, the Netroots show no signs of surrendering the ground that they have gained in the public discourse, and have become a powerful voice in the national conversation.

Social Issues and Augmented Reality

Isomorphic games (games that reflect or attempt to model reality) have been a part of both teaching and entertainment since the beginning of human intellectual history. Plato's dialogues asked his student to consider hypothetical situations. Lao Tzu presented situational advice. The oldest simulation games are chess and similar war simulations, based in part on mathematical calculations of geographical parameters and the strengths and weaknesses of various military units.

The advent of the computer age spurred the massive expansion of gaming—both fantasy games with little or no connection to the real world and isomorphs. The first isomorphs were

primarily developed by the military and used for training purposes: Simulations of nuclear strikes and counterstrikes operationalized as many factors as the feeble computing capacities of the Cold War could handle. With the beginning of stand-alone computing (free of massive tape drives and building-sized processors), an entirely new sort of game emerged. Pioneered by authors such as Sid Meiers, schooled in computer languages and gaming, games such as *Railroad Tycoon* (1990) began to appear. What separated *Railroad Tycoon* from earlier games, such as *Pacman* and *Tetris*, was the ability of the gamer to make critical decisions about the parameters of the world in which the game was played. The *God Games* (*Populous* from 1987, *Civilization*, and *Alpha Centauri*) allowed gamers to control entire worlds, planets, even galaxies on a gigantic scale and in tremendous detail. While fantasy and entertainment were central to these games, they also attempted to model reality in a way that chess, for example, never could.

By the turn of the century, the level of detail in these games was often surprising: the *Total War* series (the first, *Shogun*, was marketed in 2000) employed dozens of historians of eclectic periods to fact check and generate historical accuracy. While the early games were really only playable by single players, the protocols quickly jumped to playability over a local area network (LAN) of several players on separate computers that were linked. It was a short technological jump to allow players to play over the Internet. Internet linkages allowed for not only far more detail, but also a theoretically endless number of players because of the increased memory of games that were not resident on single machines; they "lived" on central servers, or in "the cloud."

The development of these games, and the availability of an almost unlimited platform, has led to the development of simulations that cover nearly every critical contingency for extremely complex virtual realities. Augmented reality games are a logical progression. Briefly, potentially catastrophic situations are simulated in a world that models reality in all ways other than the subject catastrophe. It then lays out the disastrous event, and offers the gamer opportunities to meet the crisis with self-developed (or in some cases, team-developed) solutions. Augmented reality is a type

of virtual reality that mimics the world environment for a user. In this reality, a user is presented with different situations, and depending on the user's actions, several scenarios are played out. The goal of augmented reality is to show a system in which the user cannot tell the difference between the real world and the created world. The benefit of this system is to show users what would happen in certain situations, depending on how they react. Augmented reality is often used in showing users what would happen in extreme cases. In these cases, the objective is to show what would happen if people do not change their actions, such as to better the world environment.

World Without Oil

Columnist Chris Dahlen voiced a much-discussed augmented reality game (ARG) concept in 2007. In his article, he hypothesized that if ARGs can spark players to solve very hard fictional problems, could the games be used to solve real-world problems? Dahlen was writing about the popular *World Without Oil*, the first ARG centered on a serious near-future scenario: a global oil shortage. Another ARG, *Tomorrow Calling*, is a beta test for a future project focused on activism with environmental themes.

World Without Oil was a one-of-a-kind game that attracted many types of gamers. It was produced by Ken Ecklund ("Writerguy"), and was a project of PBS's Independent Lens, and its Electric Shadows Web-original programming. It was the first game that featured two distinct genres: a serious game and an alternate reality game. A serious game teaches the user, and has much more value than entertainment. An alternate reality game is one in which the game is played in a cognate of the real world, but there is a bit more added to the world, an augment from the creators.

The game was open to anyone who could access the Internet, and was not bound to a particular geographic or political group. As long as one had the ability to connect to the Internet, they could play the game and help solve the problem. Over 1,800 players played the initial release of the game over a specific timeline. While only 1,800 players participated, over 60,000 watched the game play out. This game demonstrated a couple of important ideas and practices. At the

heart of the development process were several critical issues upon which the eventual success of the games would turn: Could an alternate reality game help address a current or future world problem? Can people be brought together by a game to fix a problem? Are people interested in playing a game to help others, without seeing a direct reward for their actions?

The purpose of *World Without Oil* was to create a future scenario, which may or may not come to pass. It connected many people, coming from different lifestyles and backgrounds, to come up with solutions to an oil shortage crisis. What was so unique about this game was that it allowed the players help create the story, and in return helped yield a multitude of solutions for many players. To play the game, players documented their lives as though the oil shortage occurred at the current moment. Stories and ideas were recorded daily, and they could post videos, images, or blog entries. One of the added benefits of the game was that it called people to work together to reach a common goal. By doing this, the game masters proved that people could come together in a team to begin to solve future problems before they occurred.

The result of the game was that people came together to find a stabilizing point within the crisis. At one point in the game, gas prices reached over \$7 a gallon, but at the end of the 32-week period, it stayed around \$5.60 a gallon. Even though more than 2 million people had lost their jobs, the companies in the game began to hire again. Riots occurred in most of the major cities, and the damage was just beginning to be cleaned up. Overall, the game revealed what could possibly happen if a real oil shortage occurred around the world. It was a positive experience that showed that people from all aspects of life can come together to find a common solution to a worldwide problem.

Augmented reality is a real possible solution to solve future problems today. It gives users the opportunity to face these problems head on and receive the best and worst possible outcomes in advance. By knowing these outcomes, users will be able to work together to come up with the best scenario for everyone involved. Serious ARGs introduce plausibility with third-person narrative features to attract players into the game. People

participate to experience, prepare for, or shape an alternative life or future. The games thus have the potential to attract casual players because “what ifs” are games that anyone can play. Serious ARGs may therefore be sponsored by organizations with activist or educational goals.

Their subject’s intensity and severity may lead serious ARGs to separate from mainstream ARGs in design. Instead of the challenge of normal first-person player games challenging collective intelligence to solve a game-mastered puzzle, *World Without Oil*’s puppet masters, and others who followed, acted as players to guide the collective imagination to create a multi-authored chronicle of the alternative future, purportedly as it was happening. By asking players to chronicle their lives in the oil-shocked alternative reality, the *World Without Oil* game relinquished narrative control to players to a degree not previously seen in an ARG.

In October 2008, the British Red Cross also came up with an ARG called *Traces of Hope* to promote their campaign about civilians caught in conflict. According to a press release, the game is “an experience in which on-screen characters reach out into the players’ real world.” The story will revolve around a Ugandan teenager searching for his mother during a time of civil war and unrest. The experience combines “storytelling, detective work, technology and treasure-hunt style gameplay in a compelling 21st century narrative, as players seek to reunite Joseph with his mother.” As Joseph (the teens), arrives at a camp, the game focuses on how the Red Cross’ tracing and messaging service offers the “last traces of hope” for displaced civilians searching for their families.

In 2008, the European Union funded an ARG to support motivation for multilingualism within European secondary school students called *ARGuing for Multilingual Motivation in Web 2.0*. This project is now complete, and papers on the project and the resources produced for education are to be presented at the 3rd European Conference on Games Based Learning. In 2008 and 2009, the MacArthur Foundation supported an ARG called *The Black Cloud* that was based on the book of the same name written in 1957 by Sir Fred Hoyle. The object of the game is to teach high school students in the United States about the state of the quality of indoor air. The project

is active and allows teachers to rent sophisticated air quality sensors to run the game locally.

Social Listening

Social listening consists of listening and responding to the conversation about individuals and businesses on social media Web sites. The majority of businesses have a social media presence on the Internet. Their presence is established through Facebook, Twitter, blogs, and other social media Web sites. Social media play a significant role in the lives of businesses and individuals; they allows users to create and share content. It is important to stress that every business application of social listening can be, and in many cases already is, used as a tactical component in social media political strategy. Moreover, social media sites allow users to develop a public profile, connect with a set of users who share similar interests, and view, change, and sort their list of connections and the lists of others. In other words, social media has a large impact on people’s lives.

It is the fabric that connects people socially. For example, Facebook was originally intended for relatives, friends, and others to connect on a small group level; however, it quickly burgeoned into

the social networking giant that it is today. Today on Facebook people share videos and photos, post links, and write blogs to update their profiles. A unique feature of the site is that it allows individuals to meet one another, make connections, and form bonds while making these social networks public. For businesses, social media can enhance a company's reputation and brand or destroy it. Further, social media influence how individuals interact with brands.

Monitoring social Web sites manually can be done with five tools: Google Reader for collecting the results of searches, Technorati to see blogs about a company, Google Blogsearch (to see blogs), Summize.com to see a summary of items related to a topic, Link Checker SEO Pro monitors who is linking to your URLs and what the text is composed of, and Crazy Egg to visually identify the most tracked areas of a Web page. Professional Web sites that monitor social media Web sites are available for a monthly fee, such as Radian6.com, Tracx.com, and SproutSocial.com. Listening to social media empowers businesses to have more effective Web sites. Social media provides a venue to promote Web sites, products, and services that traditional media do not, focusing a collective power.

The ideal social listener listens to multiple online communities, joins the conversation, and responds to the comments that users make online. Effective social listening can result in: initiating a dialogue between client and consumer, expanding awareness of the brand to a new audience, driving relevant links to the Web site, increasing the number of people who follow the brand, and increasing traffic to the brand's Web site. Social listening is effective in creating a conversation about a brand, which eventually could build lasting relationships. Further, social listening and monitoring social media sites can be used to respond to negative publicity about a company's product.

Responding quickly on social media sites is a good way to counteract a complaint about the company's product. It is a way of joining the conversation. In fact, Fortune 500 companies have a plan in place to deal with negative publicity. The case with Dell computers is a prime example of effective social media listening. Jeff Jarvis, a customer as well as a blogger, started a series of blogs

emphasizing Dell's lack of customer service. This event occurred in 2005. It was estimated that 50 percent of the conversations occurring about Dell were negative.

In the crisis response, Dell started a company blog called Direct 2 Dell, where it answered complaints directly from the consumer. Further, it started a new blog in 2007, called "Idea Storm." This blog allowed consumers to post new ideas and comments. Dell monitored these posts and directly responded to consumers. They also showed their follow up on some of the ideas. For example, one user in particular wanted Dell to standardize the power cord on the laptop computers. This post had the most promotions and showed how the Idea Storm site worked. The interaction of Dell with the community could be viewed on the Web site. The Dell community contributed 12,901 ideas, promoted 697,461 posts, and posted 87,605 comments. Dell implemented 389 ideas. Its blog was effective because it listened, responded, and implemented the ideas of the consumer. Idea Storm is still used, and is now carried through to Twitter. After engaging in these series of social media blogs, the negative opinion of Dell began to decrease, and it was viewed more positively in the public eye.

Clemson State University is a second example of social listening used in academe. Clemson posts on several multimedia platforms, including Facebook, YouTube, LinkedIn, and Twitter. There is a separate Twitter account for students, prospective students, staff, faculty, and alumni. There are multiple Flickr accounts, iTunes U, Google apps, and multiple online communities. It also makes use of RSS feeds and Google apps.

Further, it has its own version of a networking site, called Net Community. This site is specifically for alumni. Clemson University and Dell are much more effective because of their social listening skills. In fact, both have created conversations across the World Wide Web. Social listening caused them to create sustainable relationships.

Social Media, Adoption of

With the proliferation of social media platforms and their convergence with traditional forms of media for entertainment and information dissemination, as well as traditional forms of social interaction, the idea that one can choose whether or not to use social media is quickly becoming antiquated. As the digital divide continues to diminish and new social media platforms are created, adoption of social media will continue to become less of an option for those who want to maintain interpersonal relationships, keep up-to-date with the latest news or information, and maintain work tasks. Most people find that they enjoy the affordances offered by social media and quickly integrate social media platforms into their everyday lives.

One common reason for the adoption of particular social media outlets is that they offer entertainment. Social media allow for conversations to occur between friends in places where they might have been disruptive or impossible in the past. For example, texting can quietly occur while waiting in a doctor's office, where a phone call might be loud and disruptive. Even if a friend is not available for such synchronous interaction, social networking sites such as Facebook can

allow for several friends' status updates—often with photos, links to other sites, and references to other friends who can be linked right into the message—to be observed. Even after reviewing Facebook updates and responding to what individuals have posted, an individual is able to play games and share scores, read his or her favorite blog, respond to the author or other fans, or a host of other activities that can pass time.

Although it is easy for some to dismiss texting and social networking sites as only about entertainment, these forms of interaction also have relational functions. Reading a Facebook post or tweet offers insights into others, and they allow connection where distance or time constraints might not allow such connections to be possible. Some enjoy social media platforms because they allow a feeling of distance and comfort where sensitive topics might be more easily discussed, and social media outlets also allow for a sense of community. In fact, some adopt platforms such as Facebook because they hear other friends or family members mention that they learned something about a personal friend or relative through the site, and they did not want to feel left out from hearing the latest news. Sometimes, social media are stereotyped as the domain of the young, but these family connections will often draw users of all ages. For instance, many Skype users report that they started using the service in order to see their grandchildren and have conversations from distant locations.

Information is also secured through social media. It is not uncommon for businesses—ranging from small “mom and pop” operations to the largest of corporations—to create social media profiles where they can promote their products and establish goodwill with consumers or other stakeholders. For example, a coffee chain might tweet a link that allows those following the chain on Twitter to open a Web page with coupons or information about a promotion. The forms of connection between businesses or other organizations and individuals can also be highly personalized. For instance, members of a small business might share news that extends beyond the business, such as the announcement of an employee's engagement, or news of a baby being born. Larger organizations might refer to customers as part of their family and offer them special benefits

or offers for their loyalty. When an individual follows, “likes,” or otherwise affiliates with a business or organization through social media, it is often noticeable to friends or family members, who may also affiliate. All of this, in turn, encourages people to adopt social media platforms as a way of feeling that they can take advantage of the best offers or know when new products will become available.

Sometimes, social media are also seasonally adopted, or when particular needs arise. For example, television fans will often join a message board forum in late April when final decisions are made about what shows will be cancelled, and what new shows will air in the fall. Once that information is determined, they may abandon the forum until the following year, when that information is sought again. Online daters will often use social media only when seeking new relationships, or as

a lurker when in an unsatisfying relationship and contemplating a new one. Sometimes, people see themselves using a platform temporarily, but then find that they stay after that need has passed. For example, many who are preparing for a wedding will go to a site such as Pinterest to look for creative ideas, but then find that they want to stay when they realize how many good recipes and other shared resources are available.

The process of adopting social media platforms has become even more simplified with the development of smartphone applications (referred to as “apps”) that can quickly be downloaded and just as quickly removed. Many established social media outlets will develop an app as a companion, while other nonsocial media outlets (such as businesses or online shopping sites) will develop apps as a way of capturing a social media-like experience for customers. Still, users find

Social media are often adopted by users to avoid feeling left out from hearing the latest news about friends and family on sites such as Facebook. Being able to make connections with family can draw older users to services like Skype, where many users report that they used the service to see children and grandchildren who do not live nearby.

themselves confused about what is shared on a social media site, or even when they are actually joining one. While businesses or voluntary organizations typically do not require social media connection for patronage, some are now adopting social media platforms as a requirement for work. Many times, workplaces will have private social spaces specially tailored for employee interaction or available through platforms like the more private elements of Google, rather than use publicly available platforms.

Barriers to Adopting Social Media

However, employees or individuals are often expressly prohibited from using public outlets such as Facebook or Twitter (or are closely monitored when doing so). Individuals also report that they choose not to adopt such public platforms because they worry about others posting information or statements to their profile that would reflect poorly upon them as an employee or in a public social role or political office. That has sometimes led to people using fake names or having multiple accounts (often one that is public and another that is private) when adopting a particular social media platform. Other reasons for not adopting social media include fear of loss of private information (especially information requested when setting up an account), confusion about how a social media platform works, or the lack of a unique feature or reason for using a particular platform. Early adopters to social media outlets will often find themselves with multiple abandoned accounts as they inhabit a new social media space and then leave once they realize that others are not joining them or they realize that the platform is not a good fit for their social media needs.

The digital divide, particularly lack of access to high-speed Internet, can also prevent the adoption of social media. Social media platforms used to be developed with low-speed Internet connections in mind, but as higher speeds have become more common, social media have become more sophisticated, so those using dial-up or other low-speed connections often find themselves unable to take advantage of what these newer versions have to offer. This raises important questions about the political implications for adopting social media. As a number of institutions continue to gravitate

toward social media platforms, those who are politically engaged may find it difficult to access their causes or candidates because of the digital divide. For those who can access social media, they may find it difficult to connect to smaller sects or splinter groups affiliated with a primary political organization. They may not know the implications or nuanced viewpoints of some the groups they connect to online. These concerns aside, adoption of social media are an important and integral part of political and social issues campaigns in many countries.

Social Media, Alternatives to Commercial

Social media support the creation, upload, sharing, and collaborative creation of user-generated content. However, outcomes of participatory and collaborative information communication technologies and "prosumer" activities via social media networks are often seen as standing in opposition to commercial interests. Along with this, business leaders are figuring out how to

harness social media for marketing, sales, customer service, and other business objectives, without alienating the online user. Professor of economics at Harvard University Martin Weitzman masterminded the idea that the “share economy” might deliver even higher levels of total economic welfare for all.

One might expect a rich literature and ample empirical insights into the plethora of issues involved in social media’s potential to speed up collaborative consumption, peer-to-peer marketplaces, and private noncommercial transactions among the like-minded, and the rich array of electronic markets and networked business issues. However, a review of the literature concludes with a clear picture of the relationship between social media is a marketing tool and that the managerial economics in gaining sustainable competitive advantage through open marketplace transactions is only emerging. Can social media come to be seen as alternatives to commercial media outlets when it comes to generating economic value or welfare? Arguably, the blogosphere has opened up the paradigms of mainstream media economics toward not yet commercialized spaces of mediated interaction between humans.

Understanding Social Media Economics

Commercial mass media are struggling to find new revenue streams that can reshape their broken business model. Many scholars posit that the mass media industry’s future will be defined by experiments in monetization. New publishing business models are evolving, and companies are looking for new revenue streams, while using cost-cutting strategies as a tool to drive their businesses toward innovation. But the advertising and subscription business models that supported traditional media companies in the past appear not to be in the digital age.

Addressing the capitalization gap raises the fundamental question of how commercial media will manage to survive as traditional sources of revenue (e.g., paid display ads, subscriptions, and direct sales) shrink. Solving this issue is vital because the legacy revenue model through paid and owned media is failing. Paid advertising has found many outlets, atomized into thousands of blogs, Facebook pages, and specialized television

and radio stations, so that return on investment is becoming difficult, notably for print-only media.

Social media, on their side, has become another platform available to engage consumers. For example, digitization and convergence lead to what industry research suggests should be considered the future of television, a new media ecosystem whereby TV changes in several levels concurrently: from analogue to digital, from scheduled broadcasts to on-demand TV on the Internet, from a lean-back (passive) to a lean-forward (active) media, from straight watching to the consumption of content connected to additional services, from the sole TV viewer to the viewer being part of social networks and communities regarding the TV content, from single-screening to multiscreening.

Consequently, broadcasters are developing sophisticated social TV integration tools. They aim to drive viewer tune-in, engagement, and loyalty to boost ratings, live viewing, and ad revenue. In addition, social TV apps and multi-screen solutions open new avenues for usage. These apps let users see what their friends are watching and invite them to watch it simultaneously; chat, share, and tweet around TV programs; register through Facebook or Twitter; receive additional information on anything they see on screen through direct links in the app to information Web sites; instantly purchase products and download content (e.g., songs, series, and books); download apps to their mobile phones; and interact with the enabled adverts to enter competitions, vote, or participate in polls. Finally, and perhaps most important for companies seeking to protect and enhance business value, social media provide a point of entry into transforming the notion of business value from Michael Porter’s traditional model of the sequential value chain into a model of “value constellation,” a concept first coined by Richard Norman and Rafael Ramirez in 1993.

There, consumers and other partners and suppliers actively coproduce relationships along with the enterprise. In their model, the business model is meant to be actively co-created between the various actors involved. To support this, interactive network technologies would potentially open organizations toward customers’ involvement for value generation. Coimbatore Prahalad

and Venkat Ramaswamy have further elaborated on changes in the traditional logic of governance in electronic commerce and analytically depicted by the concept of the linear and horizontal value chain. They claim the need for producers to establish interaction platforms for “co-creating unique value with customers.” Only this would achieve sustainable competitive advantage for the business firm. Likewise, German and Scandinavian researchers in business and management have focused on “customer integration,” “value Webs,” and “interactive value creation.”

Social Media Alternatives to Commercial Media

Certainly, businesses are trying to make the most of social media in order to achieve competitive advantage through product differentiation and customer integration techniques, thereby reducing the pressure of direct competition from identical products or close substitutes. So far, however, the noncommercial nature of social media artifacts and platforms and their underlying communicative social practices help to insulate them from full commercial exploitation. Social media is about community, not commerce. They offer unparalleled opportunities for people to network and collaborate.

On the side of social media service providers, they currently offer intangible value at best, such as enhanced coverage and improved brand loyalty. However, this is not tangible cash value. But the present examination of the relationship between social media and their potential as an alternative to commercial media becomes particularly meaningful when considered in the light of calling into question what business models will have to change, should commercial media want to succeed in the future.

As for commercial television broadcasting and its transition into connected TV of the future, managers are faced with the need to satisfy users' expectations and also undertake convergence as an industrial strategy to achieve economies of scope and scale. Social media enhancements are the best drivers of opportunity to complement paid and owned media revenue models. Paid media (i.e., all forms of advertising for which a media buy is necessary), and owned media (i.e., all content assets a brand either owns or wholly

controls) are complemented by earned media revenue-generation activities through user-generated content created and/or shared by users. Still, earned media are the most elusive of the three marketing channels.

Second, with social media, consuming information becomes a collective process of sharing it with other users. Hence, public good attributes come in when information is freely shared among users, and between users and social platforms or providers. Additionally, social media are said to confer properties of merit to goods in the sense that their provision and use may benefit society at large, such that objective information, high culture, and education are promoted. For example, interactive social media applications and services may then be used as tools for strengthening citizen integration in the democratic marketplace. Overall, noncommercial social networking activities among end-users have the potential to build up commercial value, and thus business opportunities, for providers offering valuable online goods and services.

Social Media, Definition and Classes of

Social media is the term often used to refer to new forms of media that involve interactive participation. Often, the development of media is divided into two different ages, the broadcast age and the interactive age. In the broadcast age, media were almost exclusively centralized where one entity—such as a radio or television station, newspaper company, or a movie production studio—distributed messages to many people. Feedback to media outlets was often indirect, delayed, and impersonal. Mediated communication between individuals typically happened on a much smaller level, usually via personal letters, telephone calls, or sometimes on a slightly larger scale through means such as photocopied family newsletters.

With the rise of digital and mobile technologies, interaction on a large scale became easier for individuals than ever before; and as such, a new media age was born where interactivity was placed at the center of new media functions. One individual could now speak to many as easily as many could speak to one, and instant feedback was a possibility. Where citizens and consumers used to have limited and somewhat muted voices, now they could share their opinions with many. The low cost and accessibility of new technology also allowed more options for media consumption than ever before—so instead of only a few news outlets, individuals now have the ability to seek information from several sources, and to dialogue with others via message forums about the information posted. At the core of this ongoing revolution is social media. The characteristics, common forms, and common functions of social media are explored here.

Core Characteristics

All social media involve some sort of digital platform, whether mobile or stationary. Not everything that is digital, however, is necessarily social media. Two common characteristics help to define social media. First, social media allow some form of participation. Social media are never completely passive, even if sometimes social

networking sites such as Facebook may allow passive viewing of what others are posting. Usually, at bare minimum, a profile must be created that allows for the beginning of the potential for interaction. That quality sets social media apart from traditional media where personal profiles are not the norm.

Second, and in line with their participatory nature, social media involve interaction. This interaction can be with established friends, family, or acquaintances, or with new people who share common interests or even a common acquaintance circle. Although many social media were or are initially treated or referred to as novel, as they continue to be integrated into personal and professional lives they become less noticed and more expected.

Common Forms

As this overview of common forms of social media demonstrates, some are primarily used for recreation or personal connections, others for work or professional reasons, but most allow leeway for both.

E-mail. Probably the most common form of social media used in everyday life, e-mail (short for electronic mail) involves users logging into an account in order to send and receive messages to other users. Anyone who sends or receives an e-mail must have an account. Many options for free e-mail accounts are available via the World Wide Web, but many times Internet service providers will also offer free e-mail accounts with service packages, or employers will offer e-mail addresses to their employees. Most workplaces have strict rules about how e-mail accounts can be used, although many organizations report that they have no specific e-mail training. Those who work for public organizations (including politicians, professors at state universities, and administrators and assistants for government offices) are often subject to open records laws that will allow interested people or organizations to request any e-mails sent or received to a government-funded e-mail account or an e-mail account used to conduct government business.

Use of e-mail predates the Internet, with some organizations having the ability to send messages electronically within a local computing network.

As the Internet rose to prominence, sending messages across different servers also became a possibility. E-mail acts as a quick and highly reliable way to send documents or images, updates, or important details at a moment's notice, or to share one piece of information with a large number of people.

Many people face issues with spam, or unsolicited e-mail, that is usually from commercial sources. Many times spam is exacerbated by computer viruses that use e-mail programs to capture all of the e-mail addresses in a user's address book. An address book is the list of e-mail addresses that an individual saves to quickly send an e-mail to an individual or a group of people. People often divide an address book into different kinds of friends, colleagues, or family members to send correspondence to those to specific groups.

Texters. Similar to e-mail, a text uses two-way communication channel that allows individuals to quickly send a message to another person or a group of people. Although media portrayals often make it look as if texting is a particularly youthful behavior, people of all ages have adapted to texting. Still, younger individuals tend to text more often, and usually do so at a faster speed. As texting technology has improved, it is easier to text photos or to copy and paste links into texts in order to share them with others. Texters often make use of emoticons, keyboard characters to make pictures such as a smiley face (e.g., :-P), a practice that is also common with e-mail. Texters are derived from chat rooms, or computer programs that make use of the Internet to allow people to quickly talk back and forth via text characters.

Although the use of texting is often highly convenient and allows many benefits, particular attention has been paid to two texting behaviors that have led to problems: texting while driving and sexting. It is estimated that texting while driving makes a car crash at least 23 percent more likely. Sexting is most harmful when adolescent children share pictures that are later redistributed to others by the receiver. In some cases, those forwarding pictures of people under the age of 18 have been charged with child pornography. Politicians have faced scrutiny for sharing sexual messages with others, including

interns. Despite these problems, many adults report that sexting is a satisfying alternative to sexual interaction when they are away from their partners.

Blogs. The word *blog* is derived from the word *Weblog*. A blog is a Web page where an individual or group can share information or ideas with a large group of people via the Internet. It is not uncommon for a person to start a blog, and then never update it again. Some of the most successful blogs are updated on a regular basis so the followers of the blog can know when to expect new entries. Blogs cover a wide range of topics, including political issues. A common feature to blogs is a feedback forum where, after reading an entry, people can interact with both the blog author and others who have commented. Many traditional media outlets have adopted blog-like features online in order to entice readers to continue sticking with their news or entertainment offerings. For example, many newspaper stories end with the opportunity for readers to share their thoughts or comments about a current issue. These news stories—especially when about hot or particularly partisan political issues—can lead to serious debates. Because of the contentious atmosphere many blogs and news outlets find, it is not uncommon for a user to be required to register in order to participate.

One particular type of blog that has gained popularity is the microblog. The most popular microblog, Twitter, is one of the 10 most visited Internet outlets. Microblogs involve sending out very short messages—usually 140 characters or less—to the general public via a microblogging platform. People can use their accounts to read all of the messages sent by a particular user or related to a specific topic, a practice that is usually referred to as “following,” with those who are following known as followers. After Twitter became popular, sites such as Facebook also began to allow followers, meaning that public-level content could be tracked and read by someone who is not a Facebook friend. Twitter has inspired social media in many ways. One especially popular feature is the retweet, or the ability to share a tweet with others via one's Twitter account.

On a stylistic note, the hashtag, which denotes a topic, idea, or attitude using a pound sign (#)

and a word or phrase (e.g., #Lost, #firstworld-problems) was not only used on other social media platforms but in hip-hop music as well (being coined as hashtag rap after being brought to national attention by musical artists Kanye West and Drake). With over 500 million users, Twitter is also used as a gauge for what is popular, with the term *trending on Twitter* often used to describe a large-scale cultural event or topic of conversation. As such, traditional media or event managers often encourage people to tweet using a provided hashtag (e.g., #DancingWith theStars or #Lollapalooza2013).

Message boards. It is not uncommon for fans of television programs or other popular entertainment to frequent message boards that allow users to post messages about a clearly defined subject. Message boards also prove popular with people seeking social support or advice, whether they are wounded warriors trying to make sense of life after war, or someone facing breast cancer who wants to talk to someone else who has been through the experience. Advice is also offered through review sites such as Yelp that allow users to rate businesses such as restaurants.

Connection sites. Online dating is another form of social media. Users approach online dating sites—some that require paid membership and others that are free of charge—and create a profile that tells who they are and what they seek in a relationship. Some are skeptical about how honest the information displayed in an online profile is, but research shows that people are generally honest. The stigma placed on online dating sites has continued to diminish as more people continue to use them in order to meet dating partners. In addition to dating, others may use connection sites to find friends or activity partners. For example, the connection site Meet Up allows users to find activist groups, book clubs, or hobby circles. Users enter a profile, and then they can send messages to group leaders in order to learn more about the activity or see if they would make a good fit for the group.

Social networking sites. Facebook and other social networking sites are almost ubiquitous features in contemporary culture. Even those who

Young women texting in Olympia Park, Chicago. With the interactive age, instant feedback became commonplace, and the affordability and accessibility of new technology has allowed for more options for communication and consumption.

choose not to create an online profile and participate will often hear information gained from such social platforms from others. A key distinguishing feature that makes a social networking site is the fellow list of users that one connects with, usually based upon friendships, family, work relationships, or even weak-tie relationships. Initially, social networking sites were great ways to meet new people, and although that is still a possibility, many social networking sites now discourage people from adding connections they do not know. The public nature of information posted to social networking sites often allows a space for social or political viewpoints to be displayed, although research suggests that much of this political activity reinforces pre-existing beliefs—especially because people tend to be friends with people who are similar.

Games and entertainment. Online games and entertainment often carry a social dimension. Puzzle games like Bejeweled or Words With

Friends allow friends to challenge each other for higher scores, send gifts that will allow for advanced game play, or even collaborate to beat a game together. Other games such as Farmville carry social dimensions, where people can build a virtual farm, town, or business, and fellow players can patronize or lend a helping hand to each other. Many times, these games will automatically send requests to others to join in, much to the chagrin of those receiving such requests. It is becoming more common that these games will allow for some kind of chat or interaction to accompany each move.

Apps. Short for mobile applications, apps are not necessarily social media-oriented; but people can often connect through apps via another form of social media (typically Facebook), and many times apps in and of themselves have some kind of social dimension. One example is Grindr, an app that allows gay men to find other gay men who are within close proximity. Like many apps, Grindr uses a smartphone location tracker to determine where the user is, and to determine the distance between other users.

Common Functions

As the classes of social media make clear, social media have many different functions. First, they allow people to conduct identity work. When an individual puts who he or she is into a profile, it requires some kind of reflection. As individuals see reactions to their online social presence, they will consider themselves in a new light and notice that online interaction allows them to feel more open about thoughts, opinions, and inquiries. Second, social media allows people to tend to their relationships in different ways. Even if popular discourse often demonizes outlets such as Facebook or Twitter as narcissistic and shallow, research shows that they allow people, who may not otherwise be able to connect, an outlet to interact. People also report meeting some of their best friends and even spouses through computer-mediated communication platforms. Third, social media allow people to perform work functions. Sometimes, the social media is their work, such as a popular blog or someone with a large social network circle who is hired to promote events. Other times, people interact with work colleagues via

social media sites, or especially with e-mail, take care of most of their work communication using the social media outlet.

Fourth, social media allow people to seek information or share ideas. This information can range from political campaigns to local issues and disaster relief to where is a good place to buy plus-size clothing. Fifth, and often in line with information sharing, people can also offer opinions or consider the opinions of others through social media. Finally, individuals can find entertainment through such sites.

Social Media and Freedom of Information Act

On Independence Day 1966, U.S. President Lyndon Johnson signed into law the Freedom of Information Act (FOIA). Congress passed the law to give citizens the ability to request access to documents compiled and collected by executive branch government agencies. Subsequent acts and executive orders have amended the wording

of the FOIA, clarifying what information is safe to release, to whom agencies can safely release information, and the process by which citizens can retrieve documents. The act will continue to evolve in light of citizens' informational and technological needs, as well as the need for further electronic security as the government discloses more information.

Before the FOIA, both citizens and government officials were concerned about the government releasing documents containing potentially confidential information. Therefore, in addition to defining what records the government would disclose to the public, the initial bill introduced nine exemptions to deny requests for information based on sensitivity and privacy rights. For example, agencies may deny requests that might reveal a business's "trade secrets," compromise legal proceedings, or provide information specifically exempt from disclosure by statute.

Congress updated the FOIA after the Watergate scandal and passed the Privacy Act of 1974. The amendment gave citizens the right to request government information pertaining to them, and the ability to amend that information if it proved inaccurate, irrelevant, or incomplete. The act also offered individuals the chance to sue the government if one's information was improperly shared. Furthermore, the government clarified exemption number three of the FOIA with the passage of the Government in Sunshine Act in 1976, denying requests for information that hinder national defense, relate solely to personnel rules or practices, accuse a person of a crime, or interfere with legal investigations. These two acts further clarified the FOIA, and serve as the modern core of the FOIA today.

Despite the federal acts allowing for disclosure, President Ronald Reagan's Executive Order 12356 permitted federal agencies to withhold large amounts of government data. However, public outcry led President Bill Clinton to push for a more open government during his presidency. For instance, by executive order, he opened government records 25 years or older to the public. Additionally, under Clinton's directive, Congress passed the Electronic Freedom of Information Act Amendments of 1996 (E-FOIA), mandating that certain types of records created after November 1, 1996, were to be made available electronically.

The 1990s marked the foundational stages of e-government in the United States.

Although the Clinton administration furthered citizens' access to information, especially technologically, President George W. Bush restricted government transparency after the events of September 11, 2001, via executive order and the Intelligence Authorization Act of 2002. However, to assuage years of critiques against supposed instances of government secrecy, the George W. Bush administration passed the Openness Promotes Effectiveness in our National Government (OPEN) Act of 2007. One major contribution of the act was its creation of the Office of Government Information Services (OGIS) to review compliance with FOIA deadlines. Another contribution is the act's definition of a "representative of the news media" as "any person or entity that gathers information of potential interest to a segment of the public, uses its editorial skills to turn the raw materials into a distinct work, and distributes that work to an audience." This understanding of journalism is fundamental to the creation of capable citizen journalists who can spread their views via social media sites.

Recent Developments

President Barack Obama has continued to expand the U.S. government's online presence by creating the Web site <http://www.data.gov> and improving <http://www.usa.gov>, which "increase public access to high value, machine readable datasets generated by the Executive Branch of the Federal Government." Although some data still requires an FOIA request, these sites provide citizens access to more mundane government data. These developments demonstrate that the United States is attempting to develop a better e-government presence.

A major reason that the U.S. government is developing a better informational infrastructure is because citizens expect to have access to the information government collects. In fact, the number of FOIA requests is increasing each year, and in 2012, the government reported receiving 251,254 requests. Of these requests, about 40 percent of the documents were released in full, 30 percent were partially released, 30 percent of the requests were backlogged, and only 5 percent were denied in full. The highest frequency of backlogged

requests were from the Department of Homeland Security and the Department of State, while the Department of Health and Human Services provided the most full grants. However, since Obama took office, the number of backlogged requests has decreased. Part of the increased processing speed can be attributed to the sheer amount of online information already available, as well as the increasingly well-developed infrastructure of government agencies creating and updating electronic records.

Potential Improvements

Access to information is not necessarily enough, as the data the government provides must be provided in a timely manner, in a usable format, and for a number of purposes. In order to improve the release of government documents, some argue that the government could utilize social media to itemize the data, make it searchable, and improve the processing time of information requests, even among federal agencies. Currently, the government often provides citizens with a PDF document or unstructured data in response to their FOIA requests, which are difficult to maneuver. Moreover, the FOIA only requires an agency to provide records in “any form or format requested by the person if the record is readily reproducible by that agency in that form or format.” Worded in this manner, the government’s focus is not on providing data in formats most useful to citizen journalists and social media users, such as records in machine-readable databases. However, using the horizontal organizational structure of social media, members of various federal agencies and the public could help refine agencies’ files by providing accurate keywords for the documents and links to other relevant documents to make them more usable.

Social media could also allow citizens to participate or follow along with government’s decision making with increased access to government documents. Following the ideology of the open source movement, open access to information is a way to ensure accountability with elected officials. In order to ensure such participation, information must be timely, comprehensive, high quality, relevant, and reliable. Those in favor of increased disclosure contend that FOIA offers the potential for government documents to be released and shared

for such accountability checks, especially encouraging collaboration among people with expertise. Citizen journalists are one group that could freely associate with the data to find new ways of governing, fix budgets, or commend the government for a job well done because social networking is a tool that allows citizens to make such connections.

It is important to note, however, that this may be in practice a much more complicated issue than it seems in theory, and one that may not “play” the same way across the entire social spectrum. In particular, many privacy advocates have noted the significant downstream potential for violation of individual privacy, and in some cases, personal security, that is made possible by access to public information that has been cross-referenced in a way not possible before the computer age. Of special concern is personal information that is then linked to physical location via GPS technology, which makes patently undesirable behaviors such as stalking and identity theft much easier to commit.

Although the process to obtain information under the FOIA is still cumbersome, the government must first produce an easy way to ensure that there is no national security information in the body, by statute or executive order, before they can release some of the more sensitive information to a social media outlet in readable formats. However, the government could benefit from an increased use of social media by data mining what individuals think is important. For instance, by monitoring Web traffic during normal and crisis periods, such as weather-related or traffic disruptions, the government could assess the type of information that individuals find important, as well as which individuals use the Web for data. This would take far less time and money compared to traditional types of research.

Conclusion

The right to access information is fundamental to American liberty, as the Declaration of Independence even mentions that the separation of records from legislation was a major reason for revolt. Thus, as information sharing evolves alongside technology, the government must evaluate how it shares information with the public. Although various agencies and the White House have experimented with social media, the FOIA

does not discuss the procedures or limitations on using social media to disclose information.

As many FOIA requests contain the most politically sensitive or controversial information, amendments to the FOIA process need to be made in order to ensure that security concerns are addressed before releasing information onto a social media platform. With rigorous planning, preparation, and monitoring, citizens are much more inclined to believe that government could effectively use social media. A divide exists between those who prefer the right to information and those who believe in the right to privacy and security. With careful planning, and by updating the laws, the FOIA could benefit by using social media to disseminate information.

Social Media Career Wreckers

Facebook, Twitter, and other Web sites can help or hinder the careers of new and seasoned professionals. Social media career wrecks are common occurrences in the Facebook era. Professional athletes, politicians, lawyers, teachers, and other professionals are not immune to the potentially negative career implications of social media. Social media career wreckers can emerge

in different forms, can result from unflattering pictures or posts, and be perpetuated by negative reviews or lack of endorsements.

Examples

When individuals post information from personal digital devices or personal computers that may feature multiple profiles, the individual might post a personal social media post from a company or organizational account. For example, Scott Bartosiewicz, a social media manager for a media agency, posted a tweet about one of his clients, Chrysler, and how "in #motorcity, no one knew how to [expletive] drive." When he discovered that the post emerged from the wrong account, he stated that the account was compromised, and that the company was working to resolve the matter. After the company discovered the tweet, Bartosiewicz was fired from the agency. Bad links can also lead to a social media career wreck. One of the social media spokesmen for Meg Whitman's political campaign posted a tweet that contained an incorrect hyperlink. This hyperlink led followers to a video of a Japanese man named J. L. Freaks, who dressed like a cross-dresser and played the guitar.

Social media content can also lead to the end of someone's career. A police officer from Fort Lauderdale posted a rant on his Twitter feed against his constituents, which including welfare recipients and teenagers. His tweets eventually resulted in the end of his career as a police officer in the Fort Lauderdale Police Department. CEOs are not immune to the negative implications of their social media posts and public perception of the posts. The CEO of Go Daddy, Bob Parsons, tweeted a picture of himself and his recent hunting kill, an elephant in Zimbabwe. Animal rights groups were outraged by the tweet.

Unflattering Pictures or Posts

Unflattering pictures or posts can emerge from first-hand social media posts (directly from the individual—potentially in the form of social media posts made while drinking) or second-hand (or third-hand) social media posts (posts from people who are with the individual, or posts focused on secondhand information). Social media posts can also include pictures, especially profile pictures (the main picture on the

individual's social media profile). This picture is seen by viewers of the individual's public and private social media profile. Consequently, this picture could mean the death of an individual's positive perception in the lives of others. This picture is a glimpse into an individual's personal life, and their perceptions of their personal life may not be correct. These profile pictures might emerge in the following categories: the party picture, the provocative picture, the pet picture, and travel pictures. Recently, Web sites have been launched to prevent social media blunders. One site, the Social Media Sobriety test, enables users to install an extension on their Internet browser or the app on their cell phones to prevent social media posts during a certain time period. From Facebook and Twitter to YouTube and Tumblr, users can program their devices in this way.

Meg Whitman in 2009 at the Tech Museum in San Jose, California, during her campaign for governor of California. Her campaign became known for a tweet with an incorrect hyperlink that led to a video of a cross-dressing guitar player.

Negative Reviews and Posts

Social media Web sites like LinkedIn enable users to create a professionally based social media profile and to gain endorsements from other users. These endorsements serve as virtual references for individuals, and can help others boost their online and offline careers. Individuals on LinkedIn who do not have as many endorsements may not be perceived as desirable as their endorsed counterparts. In addition, individuals who receive negative endorsements have the option of erasing their endorsement, but individuals need to constantly check their social media profiles. In addition to LinkedIn, other Web sites like Yelp and review-based sites can enhance or devastate the career of service-based entrepreneurs.

When negative reviews are posted, the entrepreneurs sometimes have the option to delete the post, retaliate, or post a response. Any of these options can negatively impact the customer–client relationship, and/or contribute to a “social media career wreck.” Social media can also have a negative impact on individuals who do not have a social media presence. Other individuals can contribute negative posts on Facebook or Twitter, and while these posts may be true or untrue, they can negatively impact an individual's career. If someone experiences social media career wrecking posts, they might have to divulge these posts in future job interviews. This information might need to be revealed in a way that would not detract from the individual's candidacy. Sometimes, the individual can post favorable comments on industry specific blogs to potentially cover negative social media results that emerge during a Google search.

Social Media Noise

The term *social media noise* refers to information overcrowding in networked environments, especially the rapid proliferation of unattributed, superfluous, and often redundant messaging that can explode around any given social media meme, including those the political arena. As a side effect of the digital era, the phrase captures the user experience of extraneous chatter cluttering the social media "airwaves."

As a sociological concept, it is reminiscent of the term *information overload*, which describes situations in which "listeners" are so bombarded by a constant stream of messages that they actually cannot handle the sheer volume of material, and eventually "tune out." Similar consequences emerge when social media noise contributes to an overly saturated social media universe. Ultimately, social media noise exerts a negative impact on the efficacy of political messaging, per se, in that everyone involved in the political food chain—citizens, elected officials, and potential voters—develops strategies for dealing with it that do not always allow substantive material to penetrate the psychological and/or technical buffers (like advanced filtering devices and social media monitoring software) that are put in place as coping mechanisms.

Individuals around the world increasingly rely on social media to connect with political figures, seek and share information about political issues, news, and events, and organize with those who share similar political views. The number of Americans who use social media for political reasons grew with the 2008 presidential election, in which candidate Barack Obama harnessed the power of social media to connect with voters in a way that greatly surpassed that of his opponent, Senator John McCain. By the 2010

midterm elections, the number of Republican voters utilizing social media for political reasons was more balanced. Social media is of increasing importance to the global audience as well. Social media platforms have been influential in several protests abroad. This growth in social media use provides many opportunities for political messaging; however, there are consequences to using social media as well.

With myriad social networking sites and mobile applications, access to information is easier than ever before. These sites connect people despite traditional boundaries, such as geography, and bring together people of all political affiliations. "Friends" on social networking sites are very powerful in politics; if friends share information on a candidate or issue, the message is potentially more persuasive. Indirectly, friends place a spotlight on political issues and political candidates, often influencing debates and support, or lack of support, for candidates. However, this shared information is not vetted for accuracy. This is particularly problematic for politicians, as they must continually seek to separate fact from fiction for their constituents and potential voters. While social media will continue to be a platform on which political figures reach out to the public, these ever-increasing sites create confusion. It is ever more important for politicians to engage social media managers in key campaign roles to ensure that the public is updated on the politician's activities and stance on key issues, and that candidates can immediately correct misleading information.

Social media have also impacted global issues, playing a substantial role in promoting and organizing political movements such as Turkey's Taksim Square protests, a movement organized in response to the government's decision to replace a green space in the center square with a shopping center. The protests were fueled by angst over years of public discontent with the government. The social media response to the Taksim Square protests generated more than 2 million tweets in the first 24 hours of the protest, with consistent tweets thereafter. While the protests generated a large social media response, social media were used as a means to replace Turkey's more traditional forms of media, with Turkish protesters tweeting to others to "turn off the television." This plea from protesters to shun traditional media and

rely on social media for news provided protesters with a forum to describe events as they unfolded in Turkey. Rather than inundate the Turkish public with confusing messages, protesters sought to guide the public to social media messages.

Social media also allows political protesters to organize across borders. During the Arab Spring revolutions, social media played a vital role in organizing individuals across north African and Middle Eastern countries. Residents relied heavily on blogs, Facebook, Twitter, YouTube, and the WhatsApp application to spread their political messages. The revolutions were heralded for relaying expectations, discussing strategy, and providing breaking news to the public in a way that was organized and unified, rather than confusing and disjointed, which is often the case when organizing people online, across geographic boundaries, and with large amounts of information. Often, social media noise—increased social media presence—preceded major events in the revolution. The Arab Spring movement highlighted the role of social media as a tool for bringing together like-minded but socially fragmented individuals to unite for a single politically motivated cause.

Social media noise can create confusing, often misleading information on both individual and group levels. Thus, it is imperative that politicians, governments, and constituents be aware of the impact of social media on political outcomes.

Social Media Optimization

Social media optimization (SMO) is the strategic use of interactive Web-based and mobile technologies to make information highly visible and easily disseminated across social networking sites. These technologies, also called Web 2.0, encompass a combination of user-generated content on wikis and blogs, social news and social bookmarking sites, as well as RSS feeds and social networking sites such as Twitter, Facebook, Google+, Pinterest, YouTube, and Instagram that reuse, remix and repurpose content with the intention to generate viral publicity or become widely circulated.

In the past decade, social media has changed not only how individuals communicate with one another, but also how political campaigns are conducted. These technologies have fundamentally shifted the balance of power between candidates and voters, as well as the relationship between governments and citizens. For example, many scholars have extolled the virtues of tools like Twitter and Facebook and their use in helping to give birth to the Arab Spring movement, which ignited rebellions that resulted in the overthrow of governments in Egypt, Libya, Yemen, and Tunisia by people newly empowered through social media.

Social media has revolutionized a voter's or citizen's ability to impact political discourse and decision making and has given rise to such efforts being called open politics, politics 2.0, or

participatory politics. Politics 2.0 is the idea that participatory technologies will transform an individual's ability to follow, support, and influence political campaigns.

Previously, content producers created Web sites or blogs and used search engine optimization (SEO) techniques to improve the chances of their sites rising to the top of search engines like Google, Yahoo!, or Bing. Today those same producers rely on users of Twitter, Facebook, StumbleUpon, or Digg, and other social media to repost their content and send users back to their sites. According to social media expert Brian Solis, the metadata—or data about data—that users organize using keywords, tags, and categories to classify user-generated content is uploaded to social networks. This creates an index of online content—text, images, or video—that allows others to discover it.

Like search engine optimization, SMO can drive traffic to a Web site. However, SMO differs from SEO in a few significant ways. SEO makes use of strategically placed HTML code, keywords, and tags to drive traffic to a particular Web site; SMO takes content to users. While SEO may penalize a site that repeats its message, SMO rewards those whose messages are repeated across multiple platforms. In fact, SMO gave rise to the use of share icons that make it easier to forward an item across channels. SEO draws users to content on the site that created it, whereas SMO facilitates the flow of that content to where the influential people are. With the increase in “walled-garden” social media communities such as Facebook and Twitter, more users distribute information to their personal connections through links and retweets.

Consequently, people doing the linking have become influential arbiters of relevance, and that relevance can also mean that content surfaces high on search engine result pages, thus making it easier for others to find. As a result, social media optimization becomes the online version of valuable word-of-mouth promotion. Social media upends the gatekeeping barrier created by editors and writers, and permits citizens to tailor the conversation, which has sparked the erosion of mass media authority. Social media differs from the traditional mass media model—source-message channel receiver (SMCR)—in which a sender

transmits a message through a given channel, which is then translated and distributed with limited opportunity for feedback from the intended receiver. According to scholars Emily Metzgar and Albert Maruggi, this top-down, one-way model of mass media is ceding to interactive media technologies that give the audience more influence.

Origins

The term *social media optimization* was first coined in 2006 by blogger Rohit Bhargava, who outlined five rules for SMO that were created to distinguish SMO from the concepts of SEO, which was then the main criteria for increasing online visibility and measuring successful online currency. They have evolved to reflect the following prevailing use of the technique:

- *Create shareable content.* Previously, linkability was the measure by which content was deemed valuable. Inbound links to a specific site implied reliable and useful content. In social media, sharing may take the form of “likes” in Facebook, tweets in Twitter, or plus ones in Google Plus, each of which include links back to the source of the information. Creating content that others find useful and informative increases its ability to surface in search engines and to build a brand. It also helps the site owner or content producer to earn social authority or perceived authenticity.
- *Make sharing easy.* Use of “share” icons can encourage linking within social media tools like Digg or Diigo, or to Facebook, Google+, or Twitter. Such sharing includes creating an RSS feed to distribute content throughout social media and the Internet at large.
- *Reward engagement.* Responding to those who engage in the conversation by posting comments, retweeting, or other social sharing can help improve the performance of content. Such efforts can build a dedicated user base that proactively disseminates content.
- *Proactively share content.* This encompasses such activities as syndicating content using social tools such as RSS

feeds, Slideshare, or Scribd, or posting to profiles or sharing video on YouTube, which can extend the visibility of content. It is not enough to have content in one place. For social media optimization, content must be where the users are.

- *Encourage the mashup.* The mashup encourages others to take ownership and to revise posted content to optimize it for the social Web. This is a key to optimizing content on the social Web.

2004 Election

In every era, the transformation of media has impacted the political campaigns of those who have been able to best exploit them. For example, in the 1930s, President Franklin D. Roosevelt used the rising popularity of radio to conduct his well-received fireside chats. In the 1960s, John F. Kennedy mastered television to politically devastating effect against his presidential rival Richard Nixon in series of televised debates. In 1994, Democratic Senator Diane Feinstein of California was credited with launching the first campaign Web site. John McCain was among the first to disseminate political news and information in 2000, and used the Internet to raise \$500,000 in online donations. By 2002, more voters turned to the Internet to find political information.

In 2004, many social networking sites were just launching, and political campaigns began to recognize the growing clout of bloggers. Many were issued credentials to cover the Democratic and Republican conventions for the first time that year.

Former Vermont Governor Howard Dean's 2004 Democratic presidential bid was one of the earliest examples of SMO. Even as his supporters used Meetup.com to fuel his insurgent run, Dean used blogs to generate voter interest, to recruit, and to motivate volunteers. There was also an evident shift from an era of top-down politics that foretold the potential of participatory politics. Despite a lack of sufficient funding, Dean's strategy of Internet-based fundraising and grassroots organizing set the stage for the strategies adopted by the presidential campaign of Senator Barack Obama.

Dean's political Web strategy focused on the use of SEO to drive supporters to his candidate

Web site. In the old order of top-down politics, candidates and their consultants and advisers and the media controlled the message. In the evolving era of participatory politics, citizens increasingly have and wield more clout. Dean took advantage of those who wanted to engage with him by enlisting them to canvas for supporters, organize events, and reach out to undecided voters.

Dean was successful in creating an online presence that supporters used to carry his message to other social networks. His use of Blog for America and Meetup.com helped him raise \$20 million online, 40 percent of his campaign contributions. At one point, he had nearly 140,000 supporters on Meetup.com. Dean's campaign was even more unusual because in 2004 only 31 percent of Americans used the Internet to access political news and information, according to the Pew Internet and American Life Project. In that pre-Facebook era, the Dean campaign relied on Meetup.com, a Web site that allows users to arrange meetings around common interests. Ultimately, the supporters in his online network did not translate into votes, and he lost in the Democratic primary.

SMO and the 2008 Election

By 2008, SMO was becoming the coin of the political realm. The number of people getting their news and information from social media more than doubled, according to a Pew study. Democratic presidential candidates Hillary Clinton, Barack Obama, and John Edwards declared their candidacies online for the first time.

More politicians began incorporating the use of social media tools like Facebook, Twitter, YouTube channels, and blogs to connect with their constituents and challenge opponents. Barack Obama, a former community organizer, is credited with taking advantage of self-organized grassroots efforts to lower the cost of building a political brand and to create a sense of connection and engagement.

Obama utilized social media to build a cost-effective campaign tool that went beyond traditional political networks. He optimized information by maintaining a profile in 15 strategic online communities, including AsianAve.com, MiGente.com, BlackPlanet.com, Myspace, Facebook, Eons (a site for Baby Boomers), LinkedIn, and

Twitter. Chris Hughes, a cofounder of Facebook, created a site for Obama called MyBarackObama.com, which mimicked some Facebook features. The campaign also created an iPhone app and used text message reminders to send voters to the polls. The campaign also carefully monitored the traffic and data from the social networks. Obama's social media efforts allowed him to beat overwhelming odds, first against strong primary opponent Democrat Hillary Clinton, and then presidential challenger Republican John McCain.

The Obama campaign bypassed traditional means of communications to amass a database with millions of names, e-mail addresses, and phone numbers of people who could be instantaneously engaged. At the time, Obama had nearly 2.4 million supporters in Facebook. McCain had 620,000. On Twitter, Obama had about 112,000 followers to McCain's 4,600. On YouTube, there were more than 18 million channel views for Obama, compared to 2 million channel views for McCain, according to Pew.

These networks can be the perfect tools for politicians who zealously guard their reputations by monitoring social networks through use of the analytics in tools like Hootsuite or Tweetdeck. Although politicians have been making use of the Internet for more than a decade, their skill in optimizing social networks is relatively new.

Although Obama's efforts highlight the upside of successful social media optimization, some politicians have experienced its negative impact. Social media optimization also ensures that negative messages are easily disseminated far and wide. Such widespread distribution can have disastrous impacts on political careers.

For example, when Senator George Allen of Virginia used a slur to refer to a man of Indian descent during the 2006 U.S. midterm elections, it was caught on camera phone and went viral on YouTube. Subsequently, Allen was defeated at the polls. Similarly, New York Democratic Congressman Anthony Weiner's political career was destroyed when sexually explicit photos and messages that he texted to several women went viral. Democratic presidential candidate John Edwards's secret extramarital affair and love child found traction in social media before it reached the mainstream press. Even candidate Obama experienced the sting of social media

when midwestern voters became outraged by a comment he made about their "clinging to guns and the Bible" that was recorded and posted by a blogger for the *Huffington Post*.

On the other hand, political organizations like the Tea Party and Occupy Wall Street have successfully exploited social media optimization techniques to fuel growth in their respective organizations. For example, in 2009, citizens angered by the bank bailout formed Tea Party groups. These groups underwent new media training to learn to use blogs, Twitter, Facebook, Digg, and other social media tools to reach like-minded individuals. Their influence in the 2010 midterm election helped sweep Tea Party-affiliated candidates into office. Similarly, the Occupy Wall Street movement sprang up using Facebook, Twitter, and Meetup to coordinate events nationally and internationally. The group conducted conference calls on Skype, giving voice to what they termed the "99 percent" who felt excluded from the political discourse.

Social Media Political Gaming

Social media political games, or political Internet games, are games that critically address political and social issues and can be played online. They are considered a subgenre of games in general, and are in academic settings often referred to as serious or persuasive games. While some of these games are wildly popular and are played by many people, most games are played by a select group of players (who often are already interested in the topic of the game).

Ian Bogost coined the term *persuasive games* in 2007 as a reaction to the then (and still common) dichotomy of entertainment games versus serious games. He argued that the aforementioned terminology wrongfully suggests that entertainment games are not suited to communicate serious

messages (i.e., be used for something other than just mere entertainment). Additionally, the term *serious games* alludes to an almost exclusive focus on game content rather than on the communicating process of the specific medium. This procedural aspect of gaming is what allows for the communication of serious information in such a unique way. The term *persuasive gaming* reflects the centrality of this procedural rhetoric while at the same time focusing on those games that challenge given norms and worldviews. As such, the intent (to persuade) of the creator of the game is also important in defining it as a persuasive game.

There are many different forms of persuasive games addressing different topics and developed by different stakeholders. There are games that focus on health issues (e.g., *Re-Mission*, which shows children undergoing cancer therapy the importance of adhering to their medical treatment programs), social awareness or advocacy (e.g., *McDonalds Game*, which is concerned with the meat industry and its negative impact on society), humanitarian crises (e.g., *Darfur is Dying*, which deals with the famine in Darfur and its effect on local families), or games that promote a particular company or organization, so-called advergames. The military makes use of these games as well, both for recruiting and instruction. *America's Army* is probably the most successful and well known example in this regard. The U.S. Army, developer of the game, claims a significant increase in recruitment information requests due to this game alone.

The political subgenre of these persuasive games specifically focuses on games that challenge certain political stances or worldviews or address political issues. In order to fully appreciate and understand the different games available within this subgenre, the different parties that can develop such games should be taken into account alongside the topic or issue they address. This differentiation mainly happens on three dimensions: political institutions (such as political parties), nonprofit organizations (such as the United Nations or HopeLab), and individuals.

Howard Dean for Iowa is a game that was developed by a political institution in 2004. The American Democratic Party developed the game in light of the 2004 U.S. presidential elections,

Screen shots from the game *Darfur is Dying*, which is based on the humanitarian crisis of famine and conflict in Darfur, Sudan. Players choose their character from among members of a family that has been displaced by the crisis. Players then try to avoid the militia so that they can water crops, build huts, and keep the camp running for seven days without being captured.

and was launched around the end of 2003. Its aim was to help supporters of Howard Dean to understand grassroots outreach and to encourage them to participate in pre-caucus campaigning in Iowa. This game was successful in that it was one of the first games commissioned in light of the U.S. elections, and as such, added to the overall success of Howard Dean in harnessing the potential uses of the Internet in campaigning.

Poverty Is Not a Game was developed by the European Union for the European year against poverty and social exclusion in 2010. The game aims to raise awareness and to discuss the complex mechanisms underlying poverty, especially among youth. By playing as a young character who unexpectedly becomes poor, players can experience what it means to be poor and how certain problems relating to this can be overcome, whereas others cannot. Several lesson plans were developed and made available free of charge alongside the game for educators to use in the context of the classroom.

September the 12th is an example of a political game developed by an individual. Gonzalo Frasca developed this game based on the events after the tragedy of 9/11 in 2001. The game shows a market square where citizens and terrorists can be seen walking around. The player has the choice to shoot rockets toward the market to kill the terrorists. However, a shot, no matter how well aimed, always results in civilian casualties, which in turn leads to some of the grieving survivors turning

into terrorists as well. The intent of the creator was to persuade players of a political stance (such as that violence will only generate more violence) and to make them reflect on this issue, much like political cartoons.

In general, playing these persuasive games has shown to contribute to an increased motivation to learn, acquisition of factual and procedural knowledge about specific topics, and the further development of digital skills. After playing *Re-Mission*, for example, treatment adherence and indicators of cancer-related self-efficacy and knowledge significantly improved. More specifically, there is some evidence that suggests that playing political persuasive games contributes toward an increase in political participation and civic engagement. This is especially evident when people talk with friends and family about the issues discussed in the game (also referred to as “social facilitation” or “civic talk”). This shows that the effects and impact of playing these games should always be set in the context of everyday life, and not be regarded as isolated events.

Social Media Research Foundation

The Social Media Research Foundation (SMRF) is a collaborative effort between researchers of varying disciplines interested in creating open source tools, generating and hosting open data, and supporting open scholarship related to analyzing social media. Established in 2010, the foundation's objective includes mapping, measuring, and understanding social media usage through projects that involve the collection, analysis, and visualization of social media datasets. The foundation is comprised of faculty, students, developers, and researchers with a shared interest in understanding the interconnectivity of social media communities. Colleagues of this collaborative group include researchers with backgrounds in sociology, computer science, information technology, communication, engineering, and psychology. This interdisciplinary approach to developing social media tools and datasets has led to implications in a variety of fields, including national politics and international relations.

Social media platforms have grown in size and scope, with many developing a niche user base to separate their Web sites from others. The study of social media is still relatively new, and for social media researchers, gathering and analyzing the vast amount of social media data across a variety of platforms can be a challenge. Previously, detailed social media data metrics were only available through fee-based commercial research organizations focusing on user demographics and search habits, or funded by private research grants.

SMRF aims to make such data openly available to academics and anyone else researching these platforms, contending that exploring such data provides valuable insight into social media communities, administrators, marketers, and community members. Aside from building open tools for the collection and visualization of social media data, the goals of the SMRF are to connect users to network analysis, connect researchers to open social media data sources, archive and aggregate the results of users' collected data and analysis, and create open-access research papers and findings.

SMRF hosts open datasets relevant to the study of social media. Using NodeXL, one of the open tools developed by SMRF, researchers can upload their social media data to share with other researchers. Social media datasets can also be downloaded for further analysis. Such a feature may possibly allow another researcher to find additional information in a dataset. Also, such a feature would allow for the replication of research.

In an effort to promote continued open scholarship and collaboration, SMRF has sponsored workshops at Purdue University and the University of Maryland, in addition to online "Webshops," which are conducted to create greater reach and awareness. Researchers involved with the SMRF contribute from around the world, and many are published experts in their fields. Academic institutions represented by the collaborative include Stanford, Columbia, Brigham Young, Oxford, and Cornell universities, and the University of Maryland. Members of the organization have also published research papers on social media, social media research, and NodeXL.

SMRF has developed two open tools for analyzing social media data, ThreadMill and NodeXL. ThreadMill, as the name implies, is used to analyze the threads of conversation found in discussion forums, message boards, Twitter, and more. NodeXL is used to analyze the social networks (i.e., interconnected groups of people) based on social media data such as "likes," follows, and so forth. While ThreadMill has value, NodeXL has garnered the most attention from SMRF researchers and others. In 2011, the foundation introduced NodeXL specifically created for collecting and analyzing social media metrics.

NodeXL—designed primarily by SMRF researchers Derek L. Hansen, Ben Shneiderman,

and Marc Smith—is a downloadable open source template compatible with Microsoft Excel 2007 and 2010. The foundation suggests that integrating NodeXL into the Excel software environment makes this product easy to use for anyone familiar with the Microsoft application, and that it extends spreadsheets' capabilities to capture and analyze complex social network interaction. To access the social media data, the Excel add-on also provides built-in connections to Twitter, YouTube, Flickr, and e-mail. The Excel add-on also allows for customizable visual graphs showing interconnectedness of the group of people studied.

Use and Implications

There are many uses and implications for such social network data. The SMRF proposes that this information can offer researchers an in-depth view of social media users and their followers. For example, identifying subgroups of people who are well connected within a community and isolating important individuals in that subgroup might be of significant importance to political researchers. These subgroups are easily recognized because they are more interconnected, representing cliques of people or organizations that know each other or interact regularly, but are generally led by a small group of individuals.

In their 2009 article, "Discussion Catalysts in Online Political Discussions: Content Importers and Conversation Starters," SMRF researchers Eric Gleave and Marc Smith concluded that the flow of online information from content creators continues to be mediated by a small group of people who act as filters and amplifiers. In evaluating group cohesion and social roles within groups, researchers can pinpoint key contributors who often interact with one another, answering questions and leading the direction of conversations. Such information would be important in educational recruitment when investigating certain group interactions.

In 2012, the implications of SMRF's work expanded into international politics. In the publication *Foreign Policy*, an article about women's rights in an international context resulted in over 70,000 "likes" and 3,000 comments. A later article in *Foreign Policy* showed a NodeXL graph that indicated how polarized readers were about the article and the issue of women's rights. A NodeXL graph was also used in a later *Foreign*

Policy article about social media use during rebellions and demonstrations.

Social Media Sharing, P2P, BitTorrent

BitTorrent is a protocol mechanism that functions as a peer-to-peer (P2P) file sharing network. P2P networks are generally used as applications to share files such as audio, video, documents, electronic books, online games, conferences in real time, and similar content. The BitTorrent platform does not support streaming video.

P2P networks also connect end hosts (also referred to as peers). The protocol is used to distribute large amounts of data over the Internet. A "peer" refers to any computer that runs the file of a client. Clients prepare, request, and transmit computer files over the network using a protocol mechanism. Unlike traditional client-server networks, where servers provide the content and clients consume the content, each client functions as both a peer and a client.

Depending upon one's location, P2P protocol sharing networks dominate the traffic on the

Internet. BitTorrent, created in 2001, has over 150 million active users, and is maintained by BitTorrent, Inc. BitTorrent has more active users than YouTube or Facebook.

The BitTorrent protocol can be used to distribute large files, which reduces the strain on the original server. When many recipients need to download a file, it is an efficient method of distribution. Instead of downloading a file from a single source, BitTorrent allows users to join a “swarm” of hosts who simultaneously upload and download from the group. This is much more efficient than using a single server, enabling clients to immediately download available pieces.

When a peer downloads a file, it becomes an additional seed. The file spreads through many peer computers, and the more peers that join in, the more likelihood there is of a successful download. The BitTorrent protocol can also work with a desktop or mobile phone. Pieces are downloaded at random and rearranged into proper order by the BitTorrent client. The client monitors which piece it has and which piece needs to be uploaded to other peers. A single download consists of pieces the same size. A file can stop downloading and resume at a later date, without losing data.

Peers in P2P networks are independent entities with no central authorizing network. As a result, P2P networks heavily depend on the resources of volunteers who contribute to the system. It is in the best interest of the peers to limit their amount of contribution because cooperation may be costly. With this being the case, some peers may be unwilling to contribute their fair share of resources. In some cases, this may lead to what is called a “tragedy of the commons.” This occurs when peers maximize their use of the utility, while the overall utility of the system decreases. Consequently, the mechanism that gives a peer incentive to contribute resources is crucial for the success of P2P systems. In such a system, it is important to be fair to peers who distribute content because it gives them incentive to contribute resources.

Among the criticisms of such systems is the argument that the BitTorrent protocol does not enforce fairness, and that “free-riding” occurs within the system. In other words, there are peers who will try to download data without first

uploading the data to other peers, trying to circumvent the system.

Social Media Strategies and Tactics

Since the 2004 elections, political campaigns have been incorporating social media as part of their outreach repertoire. The use of social media continued to grow in the 2008 U.S. presidential election as they became better integrated into campaign efforts and expanded across multiple platforms. Candidates routinely moved beyond Web sites as they maintained a presence on social media sites such as Myspace and Facebook, and shared videos on YouTube. According to the Pew Research Center’s Internet and American Life Project, 36 percent of social media users now believe that these mediums play an important role in providing political information. As such, the use of social media is now viewed as an integral part of a political campaign.

Political campaigns are interested in adopting social media because they can provide a new avenue of communication when effectively used. Extant research on the use of social media in political campaigning efforts has concluded

that social media use may have great potential to benefit campaigns. There are signs that potential benefits may arise from strategically harnessing the potential of social media. However, the true potential of using social media is not yet known because they are not being fully utilized. In fact, political campaigns have failed to understand the reasons why this context is important and what they should do with them. Although empirical research on the use of social media for political campaigning is relatively new, this area is increasingly important as social media adoption continues to penetrate all sectors of society.

Reaching Constituents

The ability to directly reach constituents is important to political campaigns because candidates require public exposure. As such, candidates are now using a variety of social media to gain unprecedented access to potential voters. Although originally thought of as a means to connect with youth, social media have gained mass appeal across generations. Due to the large number of citizens using these online networks, the use of social media is assumed to aid candidates in gaining exposure. Therefore, public officials are driven to use social media for campaign activity.

Social media is unique because these platforms are freely available for both citizens and politicians to share information and connect to one another. The social media environment also encourages direct communication between campaigns and constituents. For example, Facebook has been used to facilitate direct communication between presidential candidates and citizens. In 2012, Barack Obama drew praise by personally answering questions posed by ordinary citizens through the social media news site Reddit. These types of interactions with constituents through social media are capable of personalizing a candidate. For example, videos depicting favorable aspects of candidates, such as advertisements or news appearances, can be posted on YouTube and shared to expand reach. As such, this video-sharing social media service is acting as a free political advertising tool with massive potential for exposure.

Social media also allow political campaigns the ability to reach mass audiences outside of traditional media. Because political information is

commonly retrieved outside of traditional media, using social media in campaigns can increase candidate exposure and allow for self-promotion. Candidates who effectively use these mediums have the ability to develop a following and spread their messages. In fact, using social media can have positive effects on a candidate's poll standings, especially among lesser-known candidates. This has also been demonstrated in Australia, where smaller parties appear to have successfully used these free online mediums to impact the electorate. As such, the social media environment may increase new entrants, given the low barriers to entry, allowing them to develop a following and spread their message at a low cost. In fact, the eventual frontrunners of the 2008 presidential primaries arose from those who had the highest number of YouTube views and Myspace supporters.

Although there is evidence that social media use can provide new opportunities for reaching constituents, the norms associated with traditional media remain a dominant force. For example, the most popular political news videos on YouTube have been found to feature political elites (major party candidates) and generally consist of traditional media content. Furthermore, the number of Twitter mentions that a political candidate receives has been found to be directly related to the number of mentions a candidate receives in traditional media, as opposed to their social media activity. This indicates that while social media may change the nature of political campaigning, they may not influence public attention to the extent that many believe they are capable of.

Information Dissemination

Social media provide candidates with a new medium they can use to disseminate information. Campaigns may find these online contexts to be an effective way to communicate with supporters, explain strategies, show the inner workings of an organization, and reiterate their proclamations. As such, politicians are using social media to spread messages and directly communicate with constituents. Since the 2008 U.S. presidential election, YouTube has emerged as a significant medium for political communication. In fact, visits to a candidate's Web site are found to be positively correlated with YouTube views. This

indicates that YouTube exposure may lead viewers to engage in further information seeking. However, it is important to acknowledge that social media are not simply places for information dissemination.

Image control is especially important in political campaigns. The use of social media in campaigns has caused concern because users fear that they will have a reduced level of control over their image. The online social media environment challenges election campaign strategists in their ability to deliver a clear and consistent message and image of candidates. The open nature of social media allows them to be freely used for continuous distribution and consumption. As a result, these networks weaken the amount of control that campaigns have over a candidate's image and their message. In fact, voters' heavy use of YouTube has led some campaigns to develop unflattering or controversial video content as a tactic in ruining an opponent's image. On the other hand, losing control of one's image in this context could be seen as a strength because it may be seen as a display of authenticity.

Building and Managing Relationships

When effectively used, social media can offer political candidates the ability to build and manage relationships with constituents. In 2006, Facebook was the first to invite candidates for the U.S. Senate and House of Representatives to use the network. Social media, such as Myspace and Facebook, have been touted for affording direct one-to-one linking between politicians and constituents. In fact, supporters have been found to use Facebook to establish a personal relationship with candidates. By 2008, congressional campaigns were quickly establishing supporter groups on Facebook. Although the use of social media for political campaigns had become mainstream by 2008, a lack of understanding of how to strategically implement and effectively use this medium to benefit the campaign still remained.

Barack Obama's 2008 presidential campaign provided one of the most sophisticated strategic communication plans, using social media as part of a larger campaign effort. This campaign implemented a specialized "new media dream team" to handle various social media, including its (MyBO), to build relationships with supporters.

The campaign also worked to strategically harness the power of YouTube, Facebook, and other social media sites as a political tool. For example, the campaign employed personnel entirely devoted to the creation of YouTube videos supporting the campaign. Tactics such as this enabled the campaign to have dialogue with key publics by using different social media tools to communicate and build relationships. The campaign also worked to keep lines of communication open as it actively paid attention to online dialogue and made an effort to respond in a timely and personal manner. The social media environment also allowed supporters to directly communicate with each another about the campaign.

Social media also provides an unprecedented level of transparency and accountability for political campaigns. Transparency is an important aspect of all forms of social media because they inherently demand authenticity. Social media also enable politicians to directly communicate with the constituents, rather than through traditional media gatekeepers. For example, Barack Obama's 2008 presidential campaign used its online spaces to foster transparency as they gave volunteers access to resources such as voter files and budget information.

However, most political campaigns have not yet realized the importance of two-way communication and interaction in the social media environment. Many political campaigns have a tendency to use social media as a one-way communication tool and have failed to utilize the interactive capabilities of different platforms. For example, campaign activity on Facebook has tended to revolve around a campaign's postings, which have failed to generate meaningful communication with constituents. Political candidates have also been found to provide inconsistent social media updates, and very rarely respond to comments left on their Facebook walls. Reacting to comments may indicate a candidate's willingness to listen to voters. In fact, research has shown that candidates who react to comments are more positively evaluated by potential voters. By failing to maintain an interactive presence in this environment, candidates may be seen as not understanding the social norms of the space or appearing unauthentic. Additionally, using social media in campaigns can be difficult because there is a desire to target

a broad audience. When using social media in the same way as traditional broadcast mediums, campaigns fail to take advantage of the interactive and engaging environment. As a result, opportunities to foster relationships are lost.

Mobilization and Fundraising

Using social media can provide political campaigns new opportunities to mobilize constituents, recruit volunteers, and enhance fundraising. Additionally, social media can be used to showcase involvement opportunities for potential voters. This can lead potential voters to interact with one another and aid the campaign. When used effectively, social media can aid political campaigns in turning online enthusiasm into real-world support by gaining access to potential volunteers. Again, one of the most successful uses of social media as a mobilization tool was by Barack Obama's 2008 presidential campaign. Campaign

staff used a variety of social media platforms to engage volunteers, and actively worked to make them a part of the extended campaign staff. This allowed campaign managers to essentially create a partnership with constituents that they believe led to an increase in donations, volunteers, and voting. However, the extent to which this activity actually led people to perform these duties is unknown.

Unfortunately, most campaigns have failed to effectively utilize Facebook and other forms of social media as a mobilization tool. Although there is evidence that social media users have expressed their intent to volunteer on Facebook, those who announced their support in this medium tended to be those who were previously recruited by the campaign. Additionally, campaigns may not understand the individualized utility of varying social media services. For example, YouTube is not believed to be an effective tool for fostering

Cory Booker, then-mayor of Newark, New Jersey, speaking at the 2012 Democratic National Convention on September 4, 2012. Booker has used social media to a degree that outstripped most political peers. He communicated daily with his constituents via Twitter, where he had nearly 1.5 million followers in August 2013, and answered questions and responded to problems well into the night. In October 2013, Booker won a special election to fill the term of the late Frank Lautenberg and became New Jersey's first African American senator.

volunteer engagement, but there is reason to speculate that it could be an effective fundraising tool during election campaigns. The use of YouTube alone would not be an effective tool for political campaigns. Further, a lack of clearly defined goals in the social media context is likely the cause of the failure that campaigns have experienced when mobilizing supporters. Development and implementation of such goals should be better developed to further involve people with a campaign.

Conclusion

The use of social media for political campaigning has been investigated across a variety of platforms, such as Facebook, YouTube, Myspace, and Twitter. Empirical work on this use of social media has tended to be descriptive, and has offered limited, but seemingly positive insight on effects. There are also indications that the benefits of using social media may vary by political party. For example, research on the role of social media in U.S. politics has found that Democrats are more likely to say that social media sites are important compared to Republicans and independents. Dutch voters have been found to evaluate candidates more positively if they respond to social media comments, but these effects were noticeably stronger for voters who leaned toward the right. This may indicate that right-wing candidates can benefit more from reacting to comments. Research on the Australian federal election has found evidence that candidates outside of the two major political parties may benefit the most from social media campaigning.

Since campaigns have historically utilized a variety of media outlets, they are incorporating the use of social media into an extant multiplatform campaign plan. Political campaigns still rely on the traditional Web site as an information hub. As such, social media platforms are commonly used in conjunction with a Web site, allowing candidates to integrate a wider online presence via social media outlets. Although this approach is necessary, campaigns are still in the infancy of learning how to strategically and effectively implement social media in their multiplatform tactics to benefit the campaign. Although social media may appear to be beneficial to campaign efforts, the question remains whether incorporating social media into a campaign strategy leads

to increases in volunteers, donation, and actual voting behavior.

Obstacles hampering the effective use of social media by political campaigns include an inability to control their public image, difficulties in mobilizing online stakeholders, failure to directly interact with constituents, and a lack of strategic campaign planning in the social media context. Suggestions for political campaigns include the need to strategically integrate the use of social media. This requires campaigns to gain a comprehensive understanding of the different social media platforms available, and to plan how to use these mediums for image control, transparency, and meaningful engagement. Additionally, there is a need to use integrated social media as part of a campaign's existing multiplatform strategy and develop policies for their use.

Social Media Week

Social Media Week is one of the world's largest conferences. It was founded by Crowdcentric Media in 2009 and was the first global conference to solely focus on social media. It offers a week's worth of keynote addresses, research paper presentations, workshops, discussion panels, and networking events for members of industry. The conference highlights the social, cultural, and economic dimensions of social media. The mission of the Social Media Week organizers is to connect people and organizations by encouraging the sharing of research, ideas, and information on the role of social media in society, and by promoting collaboration among those in the field.

Two global conferences are held each year, designed to help society understand the complex role that social media play on local, national, and global levels. Thousands of individuals, industry professionals, and local organizers collaborate

to produce the weeklong conferences. Events are simultaneously held in multiple cities, including research panels, workshops, and networking sessions. These events are linked worldwide through mobile and online platforms. Social Media Week also partners with CNN. CNN facilitates the release of news, interviews, and stories to the press through its iReport platform. The iReport platform allows ordinary people to upload stories, videos, and photographs to the CNN Web site. The stories from the conference tend to focus on how social media affect the iReporters' lives in terms of entertainment, news, and political choices. Content from Social Media Week is also disseminated by journalists, industry writers, and a global blog. Past conferences have also been highlighted on a YouTube Channel. The aim is to expose how social media are transforming the lives of people worldwide.

The sharing of research, keynote addresses, and the content of the conference is largely done through the Facebook, Twitter, and LinkedIn social networking Web sites, as well as through online platforms, mobile apps, and the Social Media Week Realtime application. Social Media Week Realtime is an HTML 5 application that provides realtime infographics to online users.

In its first year, the conference was held in New York City. Since then, it has expanded to include 21 cities, including New York, Chicago, Los Angeles, San Francisco, Toronto, Vancouver, Bogotá, Buenos Aires, Sao Paulo, Rio de Janeiro, Mexico City, London, Paris, Rome, Milan, Glasgow, Berlin, Moscow, Istanbul, Beirut, and Hong Kong. Host cities are chosen based on six major factors, including (1) the size and population of the city, (2) the frequency of smartphone use, (3) the frequency of broadband use, (4) whether social media has a strong influence or not, (5) the level of social media engagement, and (6) how much of the population uses Facebook, Twitter, and other social media sites.

With most conferences, one would pay a registration fee, but Social Media Week was designed to be free. Over 80 percent of the events are free. With others, there is a minimal charge; however, one has to register for each event. Further, for those unable to attend in person, they may watch the simulcast online, or download an application for their mobile phone. Apps are available

for the Windows phone, the iPhone, the iPad, and Android mobile phones.

Some of the top 10 media events to be highlighted in recent and upcoming conferences are the Arab Spring uprisings in the Middle East. The term *Arab Spring* was coined to represent the revolution, protest, and civil unrest that began in December 2010 in Tunisia and spread to such countries as Libya, Egypt, Yemen, Bahrain, and Syria. Arab Spring activists have used social media to organize protests, spotlight government crackdowns, and criticize the injustices of their governments in a phenomenon that some claim illustrates the potential for social media to sway public opinion and transform politics on a global level.

Social Network Analysis

Social network perspectives focus on the structure of social systems and how the elements of a social system come together. Individual characteristics are only part of the story; people influence each other, and ideas and materials flow throughout the network. From the network perspective, the social environment can be expressed as patterns or regularities in relationships among

interacting units. These patterns are often called structure.

A social network is generally defined as a system with a set of social actors and a collection of social relations that specify how these actors are relationally tied together. Network analysis provides two purposes: revealing the underlying social structures, and discovering the dynamic interactions among social actors. Network analysis identifies the system's structure through examining the relations among the system components, its actors.

Computer and information systems are electronic communication networks that are structured so that data, information, and messages may be passed from one location in the network to another over multiple links—transmission lines (copper wire, coaxial cable, optical fiber, and wireless connections, including satellites) and through various nodes (generally computers). When these networks link people (or higher-level social systems such as work groups, organizations, or nations) and machines, they become social networks.

The form of network that is generated through the use of social media is a communication network, defined as the patterns of contact that are created by the flow of messages among communicators through time and space. Communication network analysis identifies the communication structure, or communication flow. Relation ties (linkages) between actors are channels for the transfer (flow) of either material or nonmaterial resources, or for an association between actors, such as a friendship tie. The ties that exist between the nodes can vary along several elements, including direction, reciprocity, and strength.

Links between actors can be measured as either directional or nondirectional. Links that are directional indicate the movement from one point to another, such as the number of e-mails one person sends to another, or the degree of "liking" one person has for another. Additionally, these links can also be symmetrical or asymmetrical. If the link is directional but there is not the same value of relation, the link is asymmetrical and lacks reciprocity. Nondirectional links simply indicate an association of two actors in a shared partnership, such as two social media users linking to a similar artifact.

The basic network data set is an $n \times n$ matrix S , where n equals the number of nodes in the analysis. A node is the unit of analysis. Each cell, S_{ij} , indicates the strength of the relationship, for example, the amount of communication from person i to person j . Relationships in networks are analyzed as directional, when possible. This method provides the directional differences between all analyzed parties, representing the communication matrix.

The central power of social network analysis is to bring to life an otherwise static social structure, and to graph the development of this structure over time. Although a static analysis can reveal a traditional organizational structure, for example, such as a hierarchical organization, the ability to identify emergent structures greatly increases the understanding of social systems and better contributes to understanding communicative behavior.

Centrality

There are many operationalizations of the centrality measure, but the most frequently used are degree, betweenness, closeness, and eigenvector centralities. The degree measure of centrality is calculated by counting the number of adjacent links to or from an actor in a network. This measure can be conceptualized as an indicator of individual activity, but it does not capture system-wide properties of the network. It does, however, represent the number of alternatives available to an individual in the network. Degree centrality may also be appropriate for capturing such power-enhancing behaviors that happen via direct interaction, such as integration and reciprocation. Likewise, degree centrality can also indicate other direct interactions, such as coalitions and the avoidance of relying on mediating actors for indirect access to resources. While a relatively straightforward measure, degree centrality provides insight into individual contributions to the interconnectedness of the overall network.

Betweenness centrality measures the relative brokerage of an individual node i by indicating the number of nodes j that need to go through i to get to other nodes k that could otherwise not be reached, that is, how many actors need to go through a particular actor to reach all other actors

not otherwise reachable. Betweenness centrality is calculated by the proportion of all geodesics linking j & k that pass through i , Σ for all nodes.

Closeness centrality for a particular node is measured by the inverse of the sum of its distances to all other nodes. The closeness measure can be used to indicate how easily, or quickly, information can spread from a particular actor to all other actors sequentially.

Eigenvector centrality is often used to indicate the influence of a particular actor in a network. It assigns relative scores to all nodes in the network, based on the concept that connections to high-scoring nodes contribute more to the score of the node in question than equal connections to low-scoring nodes. An eigenvector can be defined as a non-zero vector that, when multiplied by the matrix, yields a vector that differs from the original at most by a multiplicative scalar. Eigenvector centrality is defined as the largest eigenvector of the sociomatrix defining the network. The defining equation of the eigenvector is $\lambda v = Sv$, where S is the sociomatrix of the network, λ is the largest eigenvalue of S , and v is the eigenvector.

Strength of Ties

Strength of the ties between actors, indicating quantity of the relation, can greatly vary and has profound impact of the nature of the network. Strength of the tie can be measured as dichotomous, simply indicating the presence or absence of a link, or valued, indicating the degree of the relation (e.g., how many times per week does one person contact another).

Although much interaction is with members of close groups, often the most novel and important information comes from individuals that one has weaker ties to, generally outside of these groups. Groups of people are clustered in social networks via strong ties, and the association with each other through redundant ties allow for local clustering. This local connectivity establishes multiple independent pathways, which can provide reliable accessibility. Yet, there are also a substantial number of weak ties in networks; these are the connections that our close ties have with people that are not necessarily connected to, or have much in common, with the user. Social media has enabled people to maintain a persistent connection to many more weak ties than was previously

possible, and as such users of social media have access to a plethora of novel information.

Network Density, Centralization, and Cluster Analysis

Density is used to measure the completeness of the relations in a network, also called connectedness. Measured as the ratio of total links to possible links, density can identify networks as being sparse (relatively disconnected) or dense (relatively well connected).

Centralization measures the disparity, or variation of the individuals' centrality in a given network. The higher a network's degree centralization is, the more likely it is that few individuals are well connected, while others are less connected. Conversely, the more decentralized a network is, the more equal the members' centrality scores are.

Cluster analysis identifies clusters, also called groupings or cliques, of actors that best characterize their measured associations. To perform a clustering procedure, take an $n \times n$ matrix of similarity (S); the pair of actors with the greatest occurrence of communication is pooled to form a cluster ($C1$). Following this initial step, a new similarity matrix (S^*) is generated with the pair of actors combined as a single actor. S^* is an $n-1 \times n-1$ matrix. The procedure is repeated by adding a third actor to $C1$; or a new pair of actors combined to form $C2$. The procedure continues until all n actors are incorporated to form C_m clusters, which is inclusive of all actors. The procedure described above assumes that the distances in S are unambiguous. That is, $s_{ij} = s_{ji}$. In this case, S was made symmetrical by taking the average of s_{ij} and s_{ji} .

Structural Holes and Affiliation Networks

Structural holes have been widely studied, yet are largely based on the work of Ronald Burt. Burt's conceptualization of a structural hole is that it is a relationship of nonredundancy between two contacts, and the hole acts as a buffer. When two contacts have a hole between them, the resulting effect is that it provides network benefits that are in some degree additive rather than overlapping. Structural holes can have different effects for individuals with different attributes as well

as for organizations of different kinds. Structural holes can also be summarized as existing when two members who are not directly connected to each other also lack a common network contact. Likewise, structural holes make a network more constrained or sparse because individuals have less opportunity to access novel information and resources. Structural holes can also lead to inequality between network members and power opportunities.

In affiliation networks, represented as bipartite graphs, two nodes can be thought of as affiliated if they participate in the same group or event. Affiliation networks differ from single mode networks in several ways. Affiliation networks are dual-mode, or two-mode networks, where a set of actors and a set of events each constitute a mode. The graph is bipartite in that links go from members of one mode to members of the other. Connections among members of one of the modes (e.g., simple ties between pairs of actors) are based upon the linkages formed via the second mode.

Affiliation networks have been very useful when studying political networks, as a person's social connections may include links to other individuals, but also political groups/parties, policy votes, and social media connections (among many other examples). Much of the utility in studying affiliation networks is the individuals' membership in collectives, or social circles, which provide conditions for development of interpersonal connections. Individuals are brought together through joint participation in social events, and participation in more than one event establishes a linkage between the two events, thus overlapping group membership and allowing for the transmission of information between groups. Therefore, this can be interpreted as either actors linked by events, or as events linked by actors.

Network Analysis Software and Visualization

Most network analytic procedures and research are conducted using network analysis software, which generally provide many mathematical and statistical routines that allow the user to create, manipulate, and measure networks. Many of the social network analysis software packages include

mechanisms for the visualization of networks. Examples of user-friendly and widely available social network analysis software packages are Gephi, MultiNet, NetMiner, NodeXL, Pajek, StOCNET, STRUCTURE, and UCINET.

Network mapping procedures are used to generate sociogram maps that visually represent networks created using the above procedures. Sociograms allow for the visual analysis of network data, as well as elaborate cliques and network roles that can remain cloaked when only analyzing numerical outputs. Yet, when combined with statistical outputs, visualization can highlight structures and patterns and provide an illuminating window into social systems.

Conclusion

The science of social networks has progressed in parallel with the use of social media. The precise measurement of communicative flows has been a challenge, and the increased use of social media to manage communicative interaction has provided social network scientists with a wealth of precise and novel data.

Further, the increased analytic representation and theoretical understanding of new media and information systems provides developers with improved insights into the uses of technology to manage the resources embedded in their social networks. The science of social network analysis and the development of new and social media have coevolved as catalysts of each other's development and advancement.

Communicative technologies and social media have provided precise measures of social networks. From social networking sites (e.g., Facebook), to microblogging networks (e.g., Twitter) and global cooperation networks (e.g., CouchSurfing), the material and nonmaterial exchanges of individuals and larger social systems are recorded and largely retrievable, presenting social network researchers with powerful new data. There are four main implications of having access to social media data.

First, analysts now have access to measurements of social network relations that are more reliable than in the past. Second, the nature of the relational data is unique, allowing for the analytical exploration of network structures in ways that are pushing the boundaries of the science. Third,

analysis of network evolution is increasingly possible, since much of the data available through social media is dynamic (a historically persistent challenge when collecting network data). Fourth, dynamic network data has contributed to visualization methods that allow for the animation of social networks.

Social Networking Web Sites

Social networking Web sites (SNWs) are digital applications that facilitate social interaction and promote social networking among individuals. Sixdegrees.com was the first SNW; it was founded in 1997, inspired by the idea of "six degrees of distance" originally proposed by Stanley Milgram. Previous experiments had focused on dating or recuperating ties with former classmates, such as Classmates.com, founded in 1995. Truepeers.com may also be considered among the pioneers in this area. From these first experiences,

many different digital applications for managing personal and professional contacts have emerged and have grown to a generalized online activity in which tens of millions of users are engaged. The journal *Business 2.0* named these tools the Technology of the Year in 2003. The number of users exponentially increased; Facebook, currently the largest SNW, reached 1 billion active users in September 2012. This set of new media and platforms for social interaction has implications for how people network, manage, and operate among social contacts, as well as in political movements and community participation.

SNWs combine social networking, a list of contacts, and a personal profile. Most of them depend on friend-of-a-friend (FOAF) logic to build up online social networks. SNWs can then be used for managing personal contacts for obtaining commercial outcomes or improving professional opportunities, as well as for initiating, deploying, or maintaining interpersonal relations. Participation in SNWs usually entails sharing personal data, conventionally considered private information. However, the popularity of Web sites of this kind for social interaction has become part of wider changes in patterns of sociability and the notion of privacy.

Types

SNWs differ in their purpose. First, a broad distinction could be established between those sites with mainly a personal or a professional focus. Second, there are also significant differences in the activities of users, including sharing photos and videos, to exploring hobbies and common interests, activism or community development, or simply maintaining a relationship through mundane tasks such as status updates.

Professional SNWs aim at promoting trust and widening social networks, both considered forms of social capital that facilitate commercial relations, economic transactions, and business activities. Two different types of digital applications have been developed for this purpose. On the one hand, there are programs for the systematic analysis of professional social networks. They provide the user a general view of the personal network, improving brokerage and commercial transactions. For instance, Visible Path and Spoke are two different software packages that were

designed to help company sales forces reduce marketing cycles. Both platforms are integrated in the sales department of an organization and enable relational data storage and analysis. The data are generally obtained from e-mail, personal agendas, and meetings scheduled by vendors or the commercial department.

With this information, it is possible to draw personal network maps, or even the network of contacts of the whole organization. On the other hand, there are Web sites for sharing professional profiles, promoting new relationships, and managing professional contacts. For instance, Linked In is a Web site originally designed to facilitate networking among managers and executives, which is now open to professional profiles of any kind. From its first year of operation, it emerged as an excellent means for recruitment, obtaining expert advice, and searching for partners. Similar Web sites are Ryze.com, which also organizes face-to-face meetings, and Xing.com.

Personal SNWs are used for connecting with friends, initiating and managing personal relations, as well as flirting and dating. Friendster was one of the first cases of mass dissemination of an online networking service, with millions of users. Similar Web sites with different geographical distribution and population profiles include Orkut, with massive dissemination in Latin America; Friendzy, oriented to younger users; Tribe, which organizes social networks in forums and communities; Myspace, which evolved into a site for exchanging music; and Tuenti, for young users in Spain, among others. Most of the users of personal SNWs are young adults, who are exploring new patterns of online relationships and incorporating these new media among the contexts for interaction with members of their personal networks.

The Web site of reference among these applications is Facebook, given its global reach for networking purposes. Facebook was launched in 2004, and was initially oriented to university students. Users must register to access the site, and then they publish a personal profile and make contacts with “friends.” The profile is standard for all users, and the Web site is user friendly. Almost half of users access Facebook from mobile phones. Large segments of the young population use it every day. SNWs that have more users

registered have a cumulative advantage, offering more opportunities for interaction and obtaining social resources. As in the case of Facebook, a Web site with more users participating in networking activities will attract more users than a regular Web site, following a “rich get richer” process of network growth.

Characteristics

The Institute for Prospective Technological Studies (IPTS) has summarized the characteristics of SNWs in six basic features: presentation of one-self, externalization of data, new ways for community formation, bottom-up activities, ease of use, and reorganization of Internet geography. The first step of users in a SNW is usually to set up a profile, presenting him or herself to others. This means sharing personal information and making public personal networks to others. Therefore, these sites offer opportunities for community formation, whether based in common interests, network dynamics or social categories. Additionally, platforms like Twitter have facilitated self-organization and collaboration with others, as can be observed by real-time tweets during natural disasters, such as tsunamis, and during political conflict, such as the Arab Spring. Most SNWs require registration but are free of charge and easy to use, making them accessible to the general population. Finally, SNWs are part of a process of personalization of Internet use, so people feel that they have personal information and spaces to interact with others. In this sense, an evolution from homepages to personal profiles has been documented in individual access to the Internet.

Effects

Network effects have been described in SNW adoption and impact. The effectiveness of social networking services largely depends on the number of users associated with a particular application or Web site. A critical mass is often required in order to provide positive networking experiences to members, and in turn it is a self-reinforcing process contributing to the incorporation of new users. On the other hand, this is related to homophily processes, where members of the same platform may share with others of the same gender, language, ethnicity, and educational background.

Interestingly, individuals can distribute personal contacts in different SNWs, conforming a complex ecosystem of digital contexts for interaction. Consequently, different sites may act as diverse behavior settings, with an impact in the social dynamics deployed by members.

SNWs may serve to consolidate previous and/or close relations, or extend the social networks of members incorporating new contacts. People tend to use different media to communicate with individuals who are more relevant to them. So, friends, confidants, and providers of multiple types of social support are significantly present in the list of contacts of most of the users of networking services. This is the reason why online and face-to-face relationships are not alternative or competitive worlds, but two sides of a coin showing the multiplexity of support in diverse contexts for interaction. However, SNWs enable managing and maintaining weak links, that is to say, those relationships with lower frequency of contact, intensiveness of interaction, multiplexity of support, or affection exchange. Digital applications reduce the costs for interaction, contributing to wide, distributed, and diverse networks.

Nevertheless, the FOAF logic in which these sites are usually based has been criticized. It has been argued that social confidence and trust is not maintained, irrespective of the friend-of-a-friend chain length. The transitive property may fade when one follows the path of the friend of a friend of a friend of a friend. In fact, three or four steps in the chain may mean a huge social distance. There are also limits to the accumulation of contacts, and the aspiration of unrealistic growth can undermine the maintenance of connections that one seeks to promote. Finally, some users have reservations about sharing relational capital, and/or are worried about ensuring the privacy of information.

Privacy

SNWs offer new contexts for interaction. Personal networks are made public and visualized online. Therefore, individuals publish private data and obtain some explicit feedback on the social structures of interaction where they participate. For some individuals, they provide experience on “network effects” and the impact of social structure on behavior and social opportunities.

This is also associated with legal issues and problems regarding data management. Each SNW has terms of service regarding privacy, security, and propriety of data published online. It is not always clear who owns the data published on an SNW, and it is not always easy to delete a personal profile. The increase in advanced mobile devices has also resulted in wider access to networking applications, promoting an always-on/always-on-you culture, giving the possibility of a continuous presence and pervasive awareness of others in the network. Consequently, the boundaries between different social spaces such as “home” and “work,” or “public” and “private,” are increasingly blurred.

Finally, networking digital applications are also an environment where individuals, especially young users, explore new ways of presenting oneself to others. Research has shown the key role of this type of site for self-exploration, identity redefinition, and peer validation processes. New skills can be observed in managing the risks of a unitary identity and the complexity of multiple identities. In their relatively short history, SNWs have had major influence in the reshaping of people’s social life, promoting and facilitating different notions of “networked individualism.”

Social Security

Social Security is the popular name for the U.S. government program of Old Age, Survivors, and Disability Insurance (OASDI). The program began in 1935 as part of President Franklin Roosevelt’s New Deal legislation. The goal of the program is to provide protection from insolvency in old age.

History

President Franklin D. Roosevelt championed the adoption of a Social Security law during his first term in office (1933–37). He sought to have a program of social insurance to which workers would contribute toward their old age. The plan was to achieve a type of defined benefit insurance against old age that would put in place a safety net to prevent destitution. The plan would also put a floor on poverty and guarantee a steady flow of income that would be spent by the plan’s recipients. This portion of the plan was similar to the Townsend Plan advocated by Dr. Francis E. Townsend.

The Townsend Plan, a welfare pension program, called for paying every person in the United States 60 years old and older who was not gainfully employed \$200 per month, as long as the money was spent within 30 days in the United States. Townsend believed that the money spent by the elderly would generously stimulate the economy, aid economic recovery, and be an enormous boon to the elderly poor. The idea was immediately popular with millions. Townsend clubs were founded across the country, but President Roosevelt did not endorse the plan.

When the original Social Security Act was adopted in 1935, it was a limited retirement insurance program. As social insurance, it sought to deal with the 50 percent poverty rate among American senior citizens and reduce the suffering of widows and fatherless children. The program

was denounced by opponents as “socialism.” Secretary of Labor Frances Perkins, a major contributor to the development of the program, denied the claim.

At first, Social Security old age benefits applied to only a few people, mainly older white men, because of labor patterns at the time. Since the adoption of the law, however, its benefits have been distributed to large numbers of women and nonwhites. One of the major reasons is the change in the demographics of the labor market since Social Security was adopted.

Since the beginning of the program, debates have occurred over whether it should be a social insurance program or a social welfare program. Roosevelt did not want it to be a welfare program because he believed that it would not be a success unless adopted and maintained as a social insurance program, and that welfare and other issues should be treated separately. He also postponed a medical component until later because of concerns from the medical community.

Expansion and Modification

Since the original Social Security Act was adopted in 1935, the program has expanded to include provisions for survivors, disability insurance, unemployment benefits, temporary assistance for needy families, and Supplemental Security Income (SSI). This last program provides aid to low-income people who are either aged 65 or older, blind, or disabled.

Medical components to the Social Security program have also been added. The medical portion includes Medicare, which is Health Insurance for the Aged and Disabled. Medicare is partially paid for by users, who pay a Medicare tax. The Omnibus Budget Reconciliation Act of 1990 (OBRA-90) created the Medicaid Drug Rebate Program and the Health Insurance Premium Payment Program (HIPP). These programs sought to address the cost of prescription drugs paid for by retirees. Under President George W. Bush, the Medicare Prescription Drug, Improvement, and Modernization Act (Medicare Modernization Act or MMA) was adopted in 2003. The largest modification of Medicare in decades, it sought to make prescription drugs more affordable to retirees. The legislation met with mixed reviews, as some felt it was aimed at preserving drug company profits while

others claimed that it provided too high a subsidy to patients.

Another Social Security medical program is the State Children’s Health Insurance Program (SCHIP), which covers children. The Patient Protection and Affordable Care Act of 2010 (often called “Obamacare”) is bringing many new changes to the medical portions of Social Security.

Medicaid is a means-tested entitlement program created by the Social Security Amendments of 1965, which added Title XIX to the Social Security Act. The provisions help in partnership with state medical coverage for low-income families, the blind, aged, disabled, and pregnant women.

The Social Security Administration (SSA) was created in 2007. It is an independent agency for administering social security programs, headquartered in Woodlawn, Maryland. Most people who receive social security payments have earned them through payroll taxes. These are taken under the authority of the Federal Insurance Contributions Act (FICA). FICA taxes are then deposited into the Federal Old-Age and Survivors Insurance Trust Fund, Federal Disability Insurance Trust Fund, Federal Hospital Insurance Trust Fund, or Federal Supplementary Medical Insurance Trust Fund. Together these funds constitute the Social Security Trust Fund. Its funds have been widely believed to have been separate in a so-called locked box; however, politicians have consistently used the surplus funds for general revenue purposes.

Debate

Since the beginning of the program, Social Security has been a subject of debate. Many think that the entire program should just be a welfare program for the poor, which is contrary to what Roosevelt sought. For others, the issues have been about equality, and for others about adequacy of benefits. Still others have looked at the costs, which for employers are payroll taxes and for employees are expensive tax deductions. One important complaint was that federal workers were not covered under Social Security and this was changed in 1983.

Another controversial topic is the taxation of Social Security benefits, which has been occurring since the 1980s. Ostensibly, the taxes on benefits were to reduce the threat of insolvency for Social Security. Some critics have complained that

Social Security taxes are regressive. Milton Friedman argued that the program benefits the wealthy more than the poor. Others argue that while Social Security uses a regressive taxation formula, it uses a progressive benefit program. Low wage earners actually receive more proportionally than higher wage earners.

Some opponents of Social Security point out that it has a low rate of return. These critics would prefer a market-defined benefit that can rapidly change with fluctuations in market price. Other critics claim that Social Security has been a lie because the payroll tax rate was never to rise above 3 percent. Some have claimed that it is just an elaborate Ponzi scheme.

In 2005 President George W. Bush proposed allowing workers to divert part of their social security taxes into private investment accounts. Other leaders have called for changes in the program to make it more sustainable. There are numerous organizations involved in these battles over Social Security; most of these are now using social media to spread their messages.

Social Media and the Social Security Debate

The Social Security Administration uses Twitter, Facebook, and YouTube. Its use of YouTube is to inform retirees or those near retirement about available programs. One has retired actress Patty Duke explaining how to register for Social Security online.

Social Security advocates include veterans' organizations, disability organization advocates (such as the Paralyzed Veterans of America and AMVETS), organizations to aid the elderly, minority organizations (e.g., Latinos for a Secure Retirement), labor unions and others (such as the Alliance for Retired Americans, which is associated with unions). These groups are using Facebook, Google+, Twitter, and other forms of social media to cooperate, engage in grassroots politics, and lobby Congress. The AARP also uses social media to unify its community of members. Three of its social media links include Facebook, Twitter, and YouTube. Opponents of Social Security range from those who want to abolish the whole program to those who want to develop a partial or full privatization program. They are also using social media such as Twitter. Think tanks on the

right (such as the Heritage Foundation or Cato Institute), in the center (the Brookings Institute or Rand Corporation), and on the left (the Center for American Progress) use their permanent Web sites to provide information pertinent to the politics of Social Security, with the addition of YouTube videos and other media resources. They may encourage readers to respond by posting comments. This is in effect a blog, YouTube, Twitter, and/or Facebook combination. The same combination is used by online media, which provide "opinion" connections to Twitter, Facebook, and other social media to allow for responses to their stories.

Grassroots advocacy groups for Social Security, such as the National Committee to Preserve Social Security and Medicare (which describes itself as a nonpartisan, nonprofit advocacy group), use social media to mobilize opposition to changes in Social Security and Medicare by posting incumbent ratings, advertising their side of issues, raising campaign contributions, and endorsing candidates.

Since the expansion of social media following the 2004 election, studies have found that Americans are using Facebook or other media more, but are also more politically polarized by ideology, which leads to self-segregation. Social media users are using personal "trust filters" so people share with those they trust, but not with the public at large. Even professional sites that are open

A protester holds a sign demanding that Social Security and other benefits not be cut at an Occupy St. Petersburg (Florida) demonstration on October 14, 2011. About 300 people were in attendance, in solidarity with Occupy Wall Street in New York.

produce incivility because participants resort to ad hominem attacks instead of offering reasoned arguments for their policy positions. Analysts have expressed suspicions that some groups may be stalking social media sites in order to silence opponents through incivility. Some studies see social media as having little influence on elections or policy debates. Others see dynamic changes occurring that will affect politics, including important issues such as Social Security, as groups engage each other online.

Worldview is comparable to *Weltanschauung*, “meaning system,” “belief system,” “patterns of thought,” “perspective,” “perceptual framework,” or “cognitive orientation.” The main concern here is not merely with the intellectual or cognitive aspects of the social worlds but also with the social and subjective domains in which individuals locate and define themselves in relation to others.

The focus is on the way that ordinary people imagine their social world. It is not expressed in theoretical terms, but is manifested in images, stories, and legends. Worldview is concerned with people’s place in the universe, setting boundaries between nature and culture on the one hand, and between the local and global on the other. Worldviews, contingent on cultural traditions, are clusters of ideas, beliefs, shared meanings or understandings, and practices that render social life possible.

Though worldview represents a cultural phenomenon, it is seen as constituting social facts or collective representations impacting people’s actions. Worldview indicates the notion of thinking and acting as a group member for a group reason. This means that a group of persons can collectively share worldviews, attitudes, intentions, and goals as group members of a collectivity.

The differences in worldviews of people in different social worlds are great. Therefore, it is important for social actors, particularly politicians, to establish strategies to penetrate forms of separation and understand how other people experience their social worlds. The distinctive feature of social worlds as a unit of social organization is contingent on communication, shared action, and interaction. Mediated interaction is very important in creating and sustaining any social world. In other words, social worlds may signify a sort of social organization defined by communication and interaction, rather than physical, territorial, kinship, or formal ties. However, meeting places, coffee houses, convention sites, and street corners, among other locations, provide geographical centers for interaction in various social worlds that might include, for example, social groups or social collectivities within larger societies such as social clubs, political parties, associations, labor unions, and religious societies.

Social Worlds

The idiom *social worlds* indicates several related concepts referring to a group of people accepting, sharing, and united by common worldviews.

In contrast to the concept of formal social organization or social structure, a social world is based on negotiation, voluntary participation, and collective commitment, and not an enforced or imposed conformity. A common type of social world consists of networks of interrelated voluntary associations, including social and political parties. People are agents in making their social worlds; however, social worlds, consisting of assemblages of social actors, are not based on a centralized authority or order. Rather, social actors are freely and partially involved in certain portions of the events of any social world. As Unruh states, each social world is a universe of regularized mutual response, an arena in which there is some kind of organization that facilitates anticipating the behavior of others.

Classifications

Social worlds can be classified into small local worlds, or large and more diffuse worlds. Within this context, the term *social world* is flexible enough to include ethnic, subcultural, and trans-cultural communities. The vocabulary of most politics is pertinent to small informal units as well as to large units. However, each social unit, small or large, has a worldview characterizing its social world. Large social worlds, dispersed in space, do not completely rely on face-to-face interaction, but rather on various forms of communication, particularly new media and electronic circulation, notwithstanding the importance of spatial sites. Some social worlds, such as ethnic minorities, might have a comparatively homogeneous population, while others such as global groups (e.g., the European Union) and international political parties are heterogeneous and mixed.

Although politicians are committed to similar tasks, they have different ideologies and aspirations and interact with different social worlds, especially in pluralistic societies in which applications of various forms of communication networks are crucial. Political actors involved in distant social worlds not immediately represented on the scene may express their views or exercise their influence through mediated communication or social networks. The social world of an alien group will cease to be problematic once its worldviews are spilled out through effective communication.

Social media have had a profound effect on the social worlds and daily lives of people around the world. The widespread use of social networks has revolutionized the way that people communicate on personal, social, and professional levels. Social worlds differ from each other because their communication channels differ in range, scope, and effectiveness. For example, one-way communication tools such as radio, television, and print media are not as effective as two-way communication technologies and social networking systems such as the Internet, Facebook, Twitter, YouTube, e-mails, blogs, mobile phones, text messages, and forums that can be used to foster dialogue and express the social and political demands of individuals belonging to certain social worlds.

Social worlds are significantly different regarding the view of social and political solidarity, as well as the sense of identification perceived by their members. In the United Arab Emirates, for instance, there has been a great emphasis on social and political solidarity generated by the locals' image of themselves as a "minority" in their homeland, where the number of expatriates from various countries exceeds that of nationals or locals.

Consequently, the ruling and political elites of the United Arab Emirates, contingent on both traditional social world and modern networks, proliferate folk heritage not only to gain legitimacy but also to transform the local or tribal identification into a national identity. They are continually inventing their paradigm of heritage, signifying their social world as represented in the "inside," as opposed to the "outside."

For the Emirati people, an essential tradition is based on the perception of "our social world," or "us" (insider-national, or *muwatin*) as opposed to the social world of the "other" (outsider-non-national, or *ghair muwatin*). The dynamic factors that help disseminate the Emirati social world and related forms of social and political solidarity that help to narrow the gap between generations include such modern devices as computers, iPads, and Internet-based online heritage narratives, as well as other kinds of electronic broadcast media.

Sockpuppets

The term *sockpuppet* has come to refer to the creation and use of false online personas for public argument. The use of sockpuppets has been common for some time, and can refer to a variety of deceptive tactics used in online argumentation. The term is decidedly negative and is used as a pejorative.

Basic sockpuppets are false names in posting online comments. This would involve merely creating a false user name. In more sophisticated approaches, the user concocts or purchases fictional profiles that include images, histories, preferences, or other content testifying to the humanity of the account owner. This sort of sockpuppet use would be ideal for engaging in online arguments, often through comment sections relying on third-party validation. The sockpuppet would allow the user to avoid being labeled as potentially self-interested, or to position the false identity as being more involved in, or possessing information related to the dispute at hand. Sockpuppets create a form of synthetic word of mouth. In this sense, the sockpuppet provides argumentative resources as it allows a single message or argument to come from persons who would seemingly hold different perspectives. Many sockpuppets created by individuals outside an organized campaign, intended to incite argument, would tend to be of this type.

Other sockpuppets are less personal, and take the form of members of a crowd. A sockpuppet user could purchase thousands or tens of thousands of online identities for the purposes of providing the image of support, a crowd of often silent puppets. Commonly, this comes through the purchase of large numbers of followers on social media services. Due to the logistical difficulty of managing this large number of accounts without detection, these are often dormant accounts. As social media trends are news stories in and of themselves, it is not uncommon to read stories about the political use of social media, including stories that directly compare basic numbers of followers or the rate of social media activity of a campaign's supporters. This would provide an incentive for a candidate to purchase sockpuppet followers as a strategy for persuading the press that it has more grassroots support than in reality.

Sockpuppets purchased for the purposes of being part of a crowd tend to be passive, not sending messages or making additional connections. Sockpuppets used for other argumentative purposes are often of a single mind and have very short relational histories. Given the propensity for persons and news agencies to recognize and disregard the activity of sockpuppets, more advanced techniques for creating sockpuppets and managing them will appear in the future.

A more formal name for the activity of deceptive false identities in computer science is the Sybil problem. Sybil was a mythical character exhibiting multiple personalities that would provide verification for the information in the other personalities' deceptions. Sockpuppets used in an argument can be used to as a form of Sybil character, verifying information for each other. A number of technologies have been proposed for filtering out Sybil characters; however, these generally raise barriers for access to systems and are potentially expensive, although development is ongoing.

The impact of the public discovery of sockpuppet use is often of greater magnitude than the supposed good of the deception. The likely argumentative gains for any individual sockpuppet are extremely limited; the embarrassment and reputational damage from being publicly involved in deceptive activity is great. For example, a Wikipedia editor found to be engaged in sockpuppetry

faces permanent stigma, and possibly other sanctions. Given the poor perception of sockpuppets (and their users) it is not uncommon to see the accusation of sockpuppetry as a political attack in online comment thread debates.

In the future, sockpuppets will become more advanced, with the eventual goal of passing a simple Turing test and effectively persuading the public both of the reality of the false persona and their argument. A number of defense and other agencies have expressed an interest in automated sockpuppet systems for future use. So far, the benefits of sockpuppet use have been outweighed by the risks.

Spanish 15M Movement

Under the slogan *Toma la calle!* ("Take the streets!"), the Spanish 15M Movement has led the so-called European revolutions that were born from frustration with the global economic

crisis. The Spanish 15M movement sprang from a need to find and experiment with new forms of democratic politics. Since May 15, 2011, the date from which the movement takes its name, ordinary citizens have been mobilizing, heavily relying on the use of social networks for organization and social action. The movement has bridged generations and interest groups while drawing national and international attention to demands that ordinary citizens have made of traditional political elites. The movement uses social media, not only as a resource of information and dissemination, but also as a structure for deliberation and active participation. The movement shows in practice how activism on the streets, together with the use of new technologies, can merge to support demands to further democratize contemporary societies.

Among the countless social mobilizations that broke out around the world in 2011, the Indignados (the outraged) Movement, or #spanish revolution, as the Spanish15M is also known, set a precedent for the Occupy movements in the rest of Europe and the United States. The movement has been led by the social network and digital platform Democracy Real YA! (Real Democracy NOW!). It has found inspiration in the work of Stéphane Hessel and other social networks and digital movements, such as the Spanish Juventud Sin Futuro (Youth Without a Future), V de Vivienda (V for housing), the Portuguese movement Geração à Rasca (Precarious Generation), the Greek revolts, and most conspicuously, the Arab Spring. Initially starting as a massive, spontaneous protest creating *acampadas* (camps) in main public squares across Spain, the 15M evolved as an autonomous movement, rejecting the influence of any formal and traditional representative structure, like political parties or trade unions.

The movement shifted in strategy: It started operating at the larger national level when occupying main public squares in large cities across Spain, but it later turned to operating at the local level, organizing citizens in their neighborhoods to occupy local squares as assembly points under the rallying cry *toma los barrios!* ("Take the neighborhoods!"). This illustrates the multilevel character of the movement: its global connections with similar movements from Greece to Chile, its national and regional demands to the Spanish state as well

as the European Union (EU), and its local organization in neighborhoods.

Since its eruption in May 2011, the 15M has become the leading platform for numerous protests, mobilizations, and camps across Spain. In its manifesto, the movement declares itself to be formed by ordinary people who, despite their various backgrounds, ages, political affiliations, and interests, are outraged by the ways in which formal politics and politicians have led the management of the socioeconomic and financial crisis since 2008, privileging the interests of banks and corporations over the needs of the citizens. Frustration and anger over high and increasing rates of unemployment, further privatization of public services, and austerity measures, as well as the corruption and nepotism of political and economic elites contributed to

mobilize large sectors of the population in defense of the needs of ordinary citizens. The 15M became the platform and symbolic agent of this popular discontent. It emerged to disrupt the traditional image of politics as a realm of representation in which the legitimate actors are political parties and experts. The movement has brought politics “back to the street” and to the neighborhoods—challenging the political community involved in decision-making processes. At the same time, the 15M has imposed a demand in the public sphere for further transparency and accountability of political elites. The 15M is about politics happening not only in the institutional sphere and among elected representatives, but also among lay people who are willing to engage in decision-making processes affecting their daily lives by directly participating in street assemblies, solidarity actions, or via the use of the media.

The movement does not have political affiliation, and it is autonomously organized according to a horizontal structure, that is, its main form of organization is based on popular assemblies that often take place in squares and parks with open access to the public. Deliberation and discussions are done in working commissions and working groups that convene in direct and consensual decision-making processes. Participation in these assemblies can be concrete or virtual, since activists can also participate via Twitter. The movement also created digital encyclopedia (15Mpedia) in the ethos of Web 2.0; it is a collective and open-access production in which the history of the movement’s development can be traced, as well as its organization, working strategies, achievements, and networks.

Conclusion

The 15M is yet another expression of the urge to further democratize democracy. The movement is about democracy, but transcending its regular understanding as merely an electoral system. The movement’s demands are for increasing accountability and transparency in decision-making processes. It demands the state be more effective in recognizing and addressing the needs of its population; it denounces the vices of representation and the urgency for representatives to engage in further achieving social justice and equality, rather than protecting their privileges.

The Spanish 15 Movement, named because it began around May 15, 2011, started in a few Spanish cities and spread across the country with the assistance of social media networks. The movement attracted national and international attention.

In this sense, the 15M has become a legitimate and powerful source of opinion leaders who can articulate collective action at national and local scales in projects that range from organized struggles against the eviction of families who are unable to pay their mortgages to neighborhood brigades protecting civilians, legal and illegal, from police harassment. Local activism in neighborhoods feeds back to the general movement in its demand to promote a constitutional process in Spain that can transform the political and economic system in its totality. The 15M is an expression of public indignation, but mostly the illustration of how active citizens and their use of social media, digital networks, and public spaces, can contest traditional politics to demand real-time and real-space democracy.

international phone numbers. The service automatically posts the voice messages as tweets on the Speak2Tweet account on twitter. The tweets contain a link to the audio message and a hashtag of the country from which the phone call was made. The service was launched on January 31, 2011, to allow Egyptian protesters to circumvent the Internet blackout enforced by the Egyptian government. Although the service was initially developed to support Egyptian protesters, voice-tweets were also sent from other countries in the Middle East and north Africa, such as Bahrain, Libya, Algeria, Sudan, and Syria. In November 2013, Twitter and Google relaunched Speak2Tweet in response to an Internet blackout enforced by the Assad regime, to support Syrian citizens and opposition activists who were cut off from Internet access.

Egypt

The Speak2Tweet system was developed and launched during the massive uprising against the Mubarak regime in Egypt in January 2011. On January 30, 2011, the Egyptian government cut Internet access in order to prevent the public from organizing protests. Within hours of the Internet blackout, engineers from Google and Twitter collaborated through Skype chat and developed the service based on a technology developed by SayNow, a company that Google acquired a week before the service was launched.

On January 31, 2011, less than 24 hours after Egyptians were cut off from Internet access, the service was officially launched and announced on Google's official blog. The announcement, posted by Ujjwal Singh, cofounder of SayNow, and AbdelKarim Mardini, Google's product manager for the Middle East and north Africa, expressed hope to help the Egyptian people circumvent the Internet blackout.

In the days that followed the announcement, the @Speak2Tweet Twitter account posted voice tweets from Egypt at a rate of about 100 tweets per day. The @Speak2Tweet account immediately attracted thousands of followers from around the world, many of whom retweeted the international telephone numbers that protesters can dial to send out voice tweets. To help spread the messages outside Egypt, activists also set up an open Google spreadsheet in which volunteers collaborated to

Speak2Tweet

Speak2Tweet is a service developed by Google and Twitter in the beginning of 2011 to allow people without Internet access to tweet voice messages and listen to tweets by dialing designated

transcribe the voice messages in Arabic and translate them into English, German, and French. The citizen media initiative Small World News and its project Alive, which focuses on developing the capacity of citizens to engage with the international community in crisis areas and conflict zones, partnered with Speak2Tweet. The Alive in Egypt Web site displayed a selection of audio files tweeted through Speak2Tweet by protesters at Tahrir Square, with an English translation of the messages.

Although some voice tweets reported real-time events from Tahrir Square and other places in Egypt, the majority of tweets expressed support for the protests and objection to the corrupt regime. It should be noted that there were also a number of tweets supportive of Mubarak. After the Mubarak regime dissolved in March 2011, the rate of voice tweets decreased, and after September 2011, the Speak2Tweet account was relatively dormant.

Syria

Syrian protests against the Assad regime also started in 2011. Although the Speak2Tweet service was initially launched for Egypt, in early 2011, it was also used from Syria, albeit less frequently. In the same year, the crisis-mapping platform Ushahidi incorporated Speak2Tweet to display the reports on the interactive map that documented human rights violations in Syria.

In November 2012, Internet access in Syria was cut off by the Assad administration. In response, Google and Twitter relaunched the Speak2Tweet service with new designated international phone numbers, urging Syrian protesters to call to post messages and listen to messages even without access to the Internet.

Despite Speak2Tweet's technological innovation in circumventing Internet blackouts and providing real-time crisis reporting, the service was not significantly used by protesters, who in many cases were cut off from access to landline and mobile phones, in addition to the Internet blackout.

Both Google and Twitter are American corporations. Their development of the Speak2Tweet service to assist protesters against authoritarian regimes in the Middle East and north Africa is seen as corporate adoption of U.S. foreign policy

in promoting democracy through Internet freedom. It is reported that in 2013, Speak2Tweet calls from Syria were made through satellite phones provided by the U.S. State Department to Syrian opposition activists.

Special Interest Campaigns

Special interest campaigns are mounted by special interest groups, which are organizations of like-minded individuals who share a similar position on a policy or political issue. Special interest groups have been involved in American politics as far back as the 1830s, and they have used various methods to increase awareness of their issues or topics, including media advertising campaigns, polling, lobbying, public stunts, and civil disobedience. Most campaigns are used to exert pressure on the government, which usually holds the

power to change policies or regulations. Modern special interest campaigns are making great use of social media to try to influence public opinion and change existing policies.

These types of organizations can be controversial, with some voters expressing unease with the power that special interests can hold over candidates and elected officials. It is not unusual during an election for one or more candidates to declare that they will not be accepting money from special interest groups, as this would make them seem beholden to those groups that helped get them elected.

Some well-known examples of special interest groups include the National Rifle Association (NRA), AARP, MoveOn.org, and Swift Boat Veterans for Truth. While these four groups have very different constituents and important issues, all of them have found ways to impact political elections.

Types

The Internal Revenue Service (IRS) awards tax-exempt status to special interest organizations, provided they are registered with the agency. The IRS recognizes at least three different types of political special interest groups, including 501(c) and 527 groups, political action committees (PACs). Within the 501(c) classification, there are at least 26 different categories of nonprofit groups ranging from child-care nonprofit organizations to religious, literary, and scientific groups. Some of the classifications can engage in political activities, as long as it is not their primary purpose. Others, such as religious organizations and charitable groups, are not allowed to engage in political activities.

527 groups are more loosely regulated but are allowed to raise soft money for political activities, voter mobilization efforts, and issue advocacy. Issue advocacy is when an organization uses its money and resources to bring public awareness to an issue. A group might be concerned about an environmental issue, for instance, and develop a series of online ads to promote awareness of that topic. Many 527 groups run by special interest organizations raise unlimited amounts of money to spend on issue awareness activities. 527s can be designated as federal or state, depending on the purpose of the group.

PACs raise and spend money for the expressed purpose of electing or defeating candidates. This type of organization raises what is referred to as hard money, as it is collected to be used in support of specific federal candidates and is subject campaign finance regulations. There are limits on the amount of money that PACs can give to federal candidates during individual elections.

Some organizations operate both a PAC and a 527 group so that they can raise both hard and soft money and focus attention at both the federal and nonfederal levels.

Campaigns

When these types of organizations use their resources on behalf of a candidate or a cause in an attempt to shape public opinion, it is referred to as a campaign, and their methods can vary as much as their particular causes. Traditional communication methods have included printed materials, such as brochures and issue papers, as well as radio and television advertising. Campaigns can revolve around a myriad of topics, including proposed legislation at the state or federal level, the protection of environmental resources, voter registration efforts, or the maintenance of teaching standards.

Most special interest campaigns are planned in advance and last for a set period of time. They are usually designed to catch people's attention and influence public opinion. For instance, if a campaign is planned to register voters in a particular state, that voter-registration drive will be promoted through local media, online Web sites, and various types of social media. Different communication appeals can be used, including educating the public about a specific issue, or appealing to safety, status, or American values. Appeals are matched to particular campaigns for the development of an effective message.

Special interest campaigns may or may not have a political component, but special interest groups are very active in political issues. Special interest groups often raise money for political candidates or issues, and depending on the size of the organization, they can be influential in lobbying and pushing for legislative reform.

Although special interest groups have been involved in politics in the United States for a long time, it was not until the most recent decade that

they were able to expand the scope of their influence through the Internet.

Social Media

Beginning in the 2000 presidential race, special interest campaigns used the Internet to identify like-minded members and volunteers and raise public awareness of political issues. Organizations used chat rooms available through companies such as America Online (AOL) to look for prospective members and discuss issues. Grassroots organizing was used to build membership numbers, and that led to some groups maintaining a large online presence after the 2000 election ended. E-mail lists were developed as a way to keep in touch with members and exchange information.

The number of people using the Internet grew from 361 million in 2000 to more than 812 million worldwide in 2004, meaning that the Internet grew 125 percent in those four years. Access to faster Internet connections helped fuel that increase, with broadband service utilized by 50 percent of those online. This increase in faster service led to easier sharing of online videos, photographs, and other larger files. Because the number of sites on the Web also dramatically increased, Americans had more reason to go online, whether it was to discuss political topics or shop. The increase in people online and the development of social media technologies helped special interest campaigns diversify their communication methods and more easily spread their messages.

Groups seeking to pressure the government on particular issues found social media to be of great value during the 2004 presidential campaign. Although still in their infancy, online tools such as blogs and discussion groups allowed special interest organizations to identify and communicate with like-minded individuals. Discussion groups had been a fixture on the Internet since the 1990s, but they began to be eclipsed by sites that were easier to use and offered more flexibility. Yahoo! Groups was a popular online community in which members could share photographs, document files, and plan and coordinate upcoming events. This type of site was a good place for special interest groups to begin to recruit new members and search for those with similar ideas.

Another popular social media outlet used in the 2004 election was Meetup.com, a social software tool created to help people with similar interests to organize local meetings. This was helpful for special interest groups as well as those opposing such groups' influence in politics. Meetup.com offered new tools that helped groups begin to do grassroots organizing all over the country, rather than just in a few geographic areas. By giving people the tools to organize, special interest groups began to grow in areas where they had previously not been effective. Democratic candidate Howard Dean used Meetup.org in his campaign, which gave it additional media attention and added to its popularity.

Special Interest Campaigns in Presidential Elections

During the 2004 presidential election, at least two high-profile special-interest campaigns gained national attention for their efforts to highlight political issues. MoveOn.org, a political action committee and advocacy group with about 3 million members, ran a series of prominent ads designed to hurt the re-election prospects for President George W. Bush. The group also developed an online ad contest that encouraged members to create and submit ads critical of President George W. Bush's administration. It tried to run the ad that won this contest during the 2004 Super Bowl, but the ad was rejected by CBS because the network said that it was an issue piece and was not appropriate for the broadcast.

Swift Boat Veterans for Truth was a 527 organization that ran a series of ads critical of Senator John Kerry's Vietnam service. The ads featured men who said that they served with John Kerry during the Vietnam War, and all of the ads featured the address of the organization's Web site, where additional material was available that related to Kerry's time in Vietnam. The ads were controversial, and some of the claims made in the ads were later challenged.

Advocates and detractors of both groups took to online blogs and traditional media to discuss the ads, making these two special interest groups among the most well-known organizations involved in the 2004 election.

During the 2008 presidential election, special interest groups began to use more social media. By

this time, YouTube had been founded (in 2005), and Facebook had evolved from a fledgling campus and regional site to a national social media outlet. Blogs had become influential in driving the national political conversation and in providing information outlets for candidates and special interest groups.

Money in Special Interest Campaigns

Money used in special interest campaigns is raised by individual organizations, often through memberships or donations. Critics have often lamented the amount of money spent in federal political campaigns, and in recent elections, special interest groups raised and spent much money on behalf of candidates or causes.

Money spent on the presidential election in 2008 totaled more than \$5 billion. It was the most expensive campaign ever, eclipsing the 2004 total by more than \$1 billion. Among the special interest groups garnering attention for their efforts during the election was MoveOn.org, which had 4.2 million members in 2008. MoveOn.org spent more than \$7 million in a campaign to tie John McCain to lobbyists, in addition to its social media efforts to influence the election through Facebook and YouTube.

The American Issues Project, which received \$2.8 million from one donor who had also given money to the Swift Boat Veterans for Truth group in 2004, turned its resources toward ads linking Barack Obama with 1960s radical William Ayers, Jr. The group also used Facebook to identify supporters and share information.

Social Media Opportunities

Although more attention was given to then-candidate Barack Obama's use of social media, special interest groups were also quick to adopt these new forms of communication. Groups established pages on Facebook and began using Twitter to spread their messages and establish grassroots organizing campaigns. Unlike a political campaign, which ends once the voting is over, special interest groups can continually engage members and like-minded individuals in online discussions and events, with their emphasis on a continuing push to make their issues more visible to the public.

Social media have provided a new way for special interest campaigns to recruit supporters

and spread messages. In addition to Facebook and Twitter, groups can now take advantage of social media such as LinkedIn and Foursquare, and they can have Web sites that stream video. Organizations also often post video on sites such as YouTube. Many groups also have developed smartphone apps for volunteers and keep lists of members' numbers for text messaging. A quick glance at current and past Facebook pages confirms that special interest groups are maintaining a political presence through social media. For example, many recent propositions placed on ballots in California were either supported or opposed by special interest groups with a page on Facebook.

State and Local Campaigns

Special interest campaigns are often pegged to state initiatives, rather than federal campaigns. For instance, before the 2004 presidential race, few people had ever heard of a 527 organization because they had mostly been involved in state races and referenda. When these groups were utilized at the federal level to get around provisions in the Bipartisan Campaign Reform Act (BCRA), many people were surprised by their ability to raise money and quickly spread messages. In that presidential race alone, there were 53 groups that received \$246 million during the 2003 to 2004 campaign cycle.

Prior to that presidential election, these special interest groups had been involved in many state issues and elections. The Progressive Majority, for instance, was created in 1999 to help elect progressive candidates across the country. It still provides political support to progressive candidates in races as small as local school boards and up to statewide races. While it once focused on traditional types of media, it now features Twitter feeds on its Web site and provides support to help candidates navigate through the Internet and the intricate maze of social media. Some groups focus on state legislation or political races, whereas others focus on lobbying efforts in state legislatures.

Special interest campaigns are as varied as the types of organizations and interests represented through their membership. They are generally comprised of individuals who are passionately interested in a specific topic and are willing

to spend their time and money trying to influence public opinion in that area. Special interest groups have adopted several types of social media into their campaigns and everyday communication with members.

Spending and Debt, Government

Government spending and debt are two sides of the same coin. On one side, government spending includes the things a government purchases, such as goods and services; on the other side, government debt is what the government owes for purchasing goods and services. Of course, the spending side is more complex as the needs of the constituencies change. As the population ages, a government may spend more on helping its citizens with medical costs while providing

an income for those same constituencies that includes a pension paid out to citizens at a certain age. The debt side can be even more complex. As a government tackles the challenges of an aging population, high levels of unemployment and fiscal crisis and setbacks can impair its ability to provide for the needs of its population. As such, governments look for other means of financing that may include bonds or long-term loans acquired from citizens, other governments in other states, or other countries. Government spending and government debt are difficult to research on social media sites because governments do not publish those numbers online. Instead, social media sites host discussions and examinations of government spending and government debt, and allow users to formulate some type of analysis of capital resources.

Government spending and debt often involves language and actions centered on concepts like budgets, deficits, surpluses, and interest. Depending on which aspect of government action one undertakes to discuss or examine, the conversation will likely land in either the camp of government spending or expenditures, or government debt or interest and principal payments on expenditures. Generally, governments operate within the three traditional branches as it relates to expenditures. Major departments of a government receive money to meet its objectives to its citizens and reallocate money for achieving those objectives.

In most countries there is extensive debate on the national budget. Prominent budget items can include national defense and security, payments to individuals to provide greater income security, retirement payments, and payments on the national debt. The payments on the national debt indicate that one of a government's expenditures includes interest payments that it owes to itself or others, and are also part of the government debt as well. Research and infrastructure maintenance are also government expenditures, but these can suffer reductions in funding due to the shift in importance of issues such, as national security or interest payments on the national debt that are immediately due. An IMF Staff Position Note published in 2009 states that age-related spending for governments has increased, taxes collected by governments around the world have failed to

meet expenditures, and in the G-20 countries, 100 to 700 percent of their gross domestic product (GDP) is devoted to government spending of one kind or another.

Types

To understand government debt it is essential to delineate the type of government debt that may occur. Internal debt is debt that governments owe to their citizens. This debt has been borrowed from citizens and secured through legislation or referendum. External debt is borrowed from abroad and owed to debtors abroad. This source of debt has spawned a host of discussions since 1990, when U.S. external debt represented over 60 percent of GDP. The U.S. debt-to-GDP ratio in 2011 was over 100 percent. Internal and external borrowing by government is no longer simply a measure used by the United States to meet its obligations to citizens through public services. Most governments around the world owe some portion of their debt to their citizens or to a foreign entity or government. Therefore, internal and external debt as a portion of government spending and debt have become very common.

Government spending and government debt can differ from state to state and region to region. Over 40 percent of the state of Idaho is designated national set-aside. As such, merely 50 percent of the state is available for trade, commerce, and the like. Government spending in a state such as Idaho would be quite different from government spending in states like Delaware, which has no designated national park areas. Government debt in Idaho would also be different and debt acquired would most likely go toward items that the state cannot supply due to its large designation of national park area. For the most part, government debt among U.S. states tends to be acquired to take care of education, health care, welfare, defense, and retirement.

Budget Types

A government chooses from a variety of options when it designs its budget for reallocation of resources. These options are generally known as budget types, and can include performance budgets, program budgets, line-item budgets, outcome-based budgets, or zero-based budgets. Depending on the need of the government, one

or more of these budgets options may be implemented and used to gauge the likelihood that objectives and goals can be met. Some governments try at all costs to not become indebted. They attempt to use budgeting options that ensure they will meet all obligations without having to borrow internally or externally. One way they do this is to use a pay-as-you-go method of budgeting that helps to keep government spending at an available level, and government debt nonexistent. This is a good method if nothing comes up that would require the government to spend all of the money it has. In times of natural disaster or a slowed economy, the pay-as-you-go method of spending and budgeting may not be adequate. If a city, state, or national government used this method as the sole method for spending, a natural disaster large enough to cause substantial damage within its borders could empty the public coffers and force the entity to borrow.

Fiscal Crises

In good times or times of surplus, governments may embark on funding projects that will increase or maintain infrastructure or economic development. In times of fiscal crisis, these projects may be abandoned in order to supply more vital public goods. Another option during a fiscal crisis is budget cuts and austerity. These entail the decrease in funding of projects or programs that take up a huge amount of government funding, but may be projects or programs that can be provided perhaps by the private sector, but at a higher cost than the government can provide. In this case, government spending decreases in an effort to stave off government debt. A country like Greece that is a part of the European Union (EU) and suffering from a fiscal crisis may be asked to implement drastic spending cuts and severe austerity in order to maintain support and funding from other EU nations. In 2012, austerity measures in Greece were so severe that they sparked protests around the country and an exodus of Greek citizens to other European countries like Germany. Although the fiscal crisis that Greece has experienced was not planned, problems like high unemployment, government spending, and a wholesale national funding crisis emerged, causing Greece to stall in its development and ability to accurately budget for the future.

Social Media

For the most part, governments around the world have only a trickle of social media employed for discussions and examinations from the public related to government spending and debt. Most of the Web sites that are posted do not engage the public in issues related to government spending and debt unless some crisis has emerged or in the event that a contentious election is approaching. Still, most governments attempt to provide their citizens with some level of input, although most of it remains symbolic.

This may be because of the fact that social media is still a new tool, and government officials are still attempting to process the uses of social media, both internally and externally. However, there is little doubt that once governments begin to understand the range of use and functional options of social media for interaction and suggestions regarding spending and debt, social media will become as common as a login and password. Info.apps.gov is a Web site provided by the U.S. Government Services Administration that provides governments with platforms for cloud computing social media options.

A Google search demonstrates how many cities around the world are building Facebook pages for immediate and consistent feedback from citizens. Some, like those in England, have used crowdsourcing, or soliciting public response, in an effort to prioritize spending cuts using the Facebook platform. For the most part, internal use of social media by governments has been in the form of records management. Wiki pages developed as Web pages or pages set up for information on particular subjects are becoming more common, and in some cases are entirely built by the very public servants working in those particular agencies or departments. In early 2011, the U.S. Coast Guard, using a platform from the former Apps.gov (now Info.apps.gov), created a Wiki Page to develop its IT strategy and summarize best practices for that strategy. Another Web site, IT Dashboard, tracks public spending to improve transparency and accountability while helping governments manage investments. The Dashboard is a tool that the public can use to track government spending on particular items while keeping up with the level of government spending and resource allocation on a specific item.

Of those countries with official government Web sites, most employ Twitter, Facebook, RSS feeds, and YouTube as part of their social media options for citizen participation and feedback. However, an expanded search will show that there are not many official Web sites that can be counted on to post anything beyond published documents as they relate to spending and debt within the social media options available on their Web sites. A few notable exceptions include England's use of social media options for citizen feedback. England's Web site Democracy UK is used by government departments to host discussion forums on spending items. In 2005, India passed a Right to Information Act emphasizing the need for data sharing and transparency. In 2012, India also passed a National Data Sharing and Accessibility Policy to emphasize the government's commitment to easy access to data for scientific, economic, and social development purposes.

The United States has a Web site devoted to cataloging each federal award, amount, and funding agency. The Web site, called USAspending, was launched in 2006 as part of a statute requirement of the Transparency Act. In 2009, President Barack Obama entered office with a number of initiatives aimed at using social media as part of the approach for reaching and communicating with the public. In the same year, his Open Government Directive was one such initiative that called for increased online publication of government information for public consumption. Agencies and departments in the government began to collaborate with universities and programmers in an effort to develop social media uses to meet the president's initiative.

In 2009, the Web site YouCut was launched as an effort by U.S. Representative Eric Cantor to seek recommendations from the public regarding which government spending to cut. For editing and sharing, Google Docs can be set up by one agency or department and sent to others for input on strategies or policies, without having to physically meet for regular input sessions. This type of collaboration saves an enormous amount of time and money by eliminating meeting times and separate task force sessions, and by employing specific experts all in real time. Google+ is also a tool used by many governments when putting together spending and debt documents for presentation

IT Dashboard, an official U.S. government Web site, "allows the general public and other stakeholders to view details of federal information technology investments . . . to provide information on the effectiveness of government IT programs."

to groups or the public. Google+ is available as an application for mobile devices or for desktops, with features such as Circles for organizing groups and the instant messaging feature for Circle groups called Huddle. Another major feature of Google+ is the ability to invite contacts from Hotmail and Yahoo! The U.S. State Department is an agency that uses Google+. The Foreign Assistance Dashboard keeps up with U.S. global aid, and allows citizens to see where their tax dollars are going in the international community. If one wanted to know the total amount of global debt the world has, a visit to the *Economist* Web site shows the global debt clock as it ticks off in real-time, up-to-date debt totals for global debt adding over \$300,000 per second. For a closer analysis of the meaning of the total, the color legend red shows states with the highest individual debt, and dark green for states with less debt.

Debategraph is also a social media tool that governments have used to assess comments and suggestions on policy issues, including those regarding government spending and government debt. Debategraph provides digital visual

mapping of the ideas and opinions of diverse groups around an issue. Despite being used by agencies, departments, politicians, and individuals seeking political office, this has been used by several governments and entities, including the United States, England, and Canada, as well as the United Nations. There have been a number of other collaborative social media tools experimented with by governmental entities around the world. Most were temporary, but some have resurfaced. A search of official government Web sites in many countries yields social media symbols unique to that particular country. Unique to Portugal is the social media tool called the "start tracker," while Morocco and Costa Rica use DIP-NOTE BLOG. These are by no means the limit to social media used by governments around the world, which may one day be even more useful when governments become more comfortable using them to collaboratively report and assess their spending and debt.

Spiral of Silence

Elisabeth Noelle-Neumann, a German public opinion researcher and professor of communications research, coined the term *spiral of silence* while trying to explain public opinion polls' failure to predict outcomes of elections in West

Germany. The spiral of silence model began as an explanation of the interaction between public opinion and voters' behavior. At the foundation of the theory lies the assumption that potential group pressure transmitted via mass media (usually in the form of public opinion data, illustrating majority opinion) forces supporters of unpopular views (about political candidates, beliefs, or ideas) to stay silent and even change their opinion. Once started, the effect amplifies itself. In this spiral-like process, the support for the popular belief grows and the minority view is increasingly silenced at every step. Mass media, as the source of information about popular beliefs, play a crucial role in this process. Emergence of the Internet and social media, while providing new channels and means for mass communication, can potentially change the nature of spiral of silence mechanisms.

Background

Last minute swings of public support for candidates in 1965 and 1972 West German federal elections, connected to the voters' capricious political attachments and their prognoses of election outcomes, puzzled Noelle-Neumann and other scholars and analysts alike. Both in 1965 and in 1972, two major parties were racing neck-to-neck to gain majority in the Bundestag (German federal diet). Voting intentions among German constituencies remained largely unchanged until the last minute. At this point, people became aware of the "expected winner" and jumped on the bandwagon. As Noelle-Neumann described it, "What had occurred ... [was] the power of public opinion. Under its pressure, hundreds of thousands—no, actually millions of voters—had taken part in what was later called a 'last minute swing.'"

"Spiral of Silence: a Theory of Public Opinion," a 1974 article in *Journal of Communication*, and a later book titled *The Spiral of Silence: Public Opinion—Our Social Skin*, lay out in detail the idea, research, data, tests, and argumentation of the spiral of silence as "a process that creates and spreads public opinion." Noelle-Neumann adopts what is described in earlier works of social psychologists as "fear of isolation" as the motive of the spiral of silence mechanism. "The social nature of human beings" stipulates the close attention paid to group judgments. Being

afraid to become social isolates, people take steps to ensure their attachment to a group. Belonging to a larger group, or winning side (the majority), boosts a person's self-confidence and reduces the risk of isolation that might follow his or her expressing an opinion. In other words, popular opinion is more comfortable to subscribe to and is more easily expressed.

"Willingness to speak out" is another cornerstone of the theory. The stronger the individual's belief is that his or her opinion is the dominant one, the more likely he or she is to express this opinion. The more vocal support a view receives, the stronger it appears. The stronger the view appears, the easier (less risky) it is to support it, and it ultimately gains more support. Triggered by the fear of isolation, vocal expressions of support for popular views and lack of support for opposing minority views set the spiral of silence in motion.

According to Noelle-Neumann, individuals use their "quasi-statistical organ" to assess their social environment and figure out the distribution of opinions, as well as amount of support for and against their ideas. People sense trends in the social weather. If the individual's view appears to be losing ground, this person would be less willing to express the opinion, and may even subscribe to a different view out of fear of isolation. At this crucial stage of environmental surveillance, mass media, as the main source of information about public opinion, come into play. Noelle-Neumann believes that individuals are dependent on mass media in their evaluation of the climate of opinion. Involving mechanisms of agenda setting (and going a step beyond by not just telling people what to think about, but also providing an assented take on what others think), media create public opinion by providing environmental pressure. Individuals respond to this pressure by expression of their support for or acquiescence to the dominant position, or silence. In describing this process, the spiral of silence theory takes a side in the debates of whether media simply retransmit public opinion, or influence it.

In Noelle-Neumann's research, cases where people were mistaken about what the popular opinion was (a condition called "pluralistic ignorance") were very likely to be, the author

suggested, a consequence of media providing a mix of viewpoints disproportionate to their strength in society. In the process, described by the spiral of silence model, what matters is the majority opinion perceived through the quasi-statistical organ and not the popular opinion itself. In her book, Noelle-Neumann suggests that pollsters are asking the wrong question. Instead of asking, "Who do you plan to vote for?" one should ask, "Who do you think will win the election?" Responses to the latter question, when analyzed for the book in public opinion data, demonstrate more consistency with ultimate election outcomes, and illustrate much clearer trends. If a current majority is considered a minority at the moment, it will decline in the future. As long as a group is perceived as a minority, people will be unwilling to express support for the group. In a reversed process, if a minority is perceived as the majority, the faction will grow, and may ultimately win popular support.

Social Media and the Spiral of Silence

Mass media, the main source of information about the majority opinion, play a very crucial role in the spiral of silence effect. According to the theory, one learns through mass media who the majority is and what their views are. Different media systems (open versus closed, strictly controlled versus liberal) in different political systems (democratic, authoritarian, and totalitarian) offer different tools that factions can use in their struggle to gain recognition as the majority, which can ultimately generate and enlarge their actual support.

While being less susceptible to external control and including a larger number of more diverse messages, messengers, and audiences, the World Wide Web in general (and social media in particular) influences the spiral of silence process. Social media provide easy, low cost, (arguably) safer access to mass audiences, which potentially should promote diversity of opinions. While representing a greater diversity of opinions, social media can reduce the fear of isolation: one could more easily find a group to subscribe to, and can for an unpopular opinion.

Research shows that spiral of silence effects are still present in the social media environment. However, the magnitude of the effect is lessened by multiple factors. Many of these factors are

determined by the nature of social media, and others are determined by distinct characteristics of their audiences. While traditional media still hold the position of the main source of information on controversial political issues, new channels of communication are growing in popularity. When it comes to authoritarian and totalitarian regimes, where the access to alternative information is limited (if not restricted), the role of social media in political communication becomes more significant. The importance of social media is higher for traditionally unpopular groups, such as lesbian, gay, bisexual, and transgender (LGBT) communities, which can gain voice now after being largely ignored by the mainstream media for a long time.

Being accepted by the popular majority becomes less significant for individuals altogether. It becomes more difficult for the majority (actual and/or perceived) to maintain status quo, which arguably contributes to social and political change. The examples of the Arab Spring and social unrest in multiple countries, backtracking to social media, provide demonstrative illustrations of the new tendency.

Splogs

Splog is a fairly new term referring to spam blogs. It is defined as any deliberate human action meant to trigger an unjustifiably favorable relevance or importance for some blog, considering the blog's true value. The purpose of a splog can be to increase the page rank or backlink portfolio of affiliate Web sites, to artificially inflate paid advertisement impressions from visitors, and/or use the blog as a link outlet to sell links or get new sites indexed.

Splogs can be broadly classified into link spam blogs and fake blogs. The former is quite common in the rest of the Web, and usually contains a high number of links to sites associated with the splog creator, which are often disreputable or otherwise useless Web sites. The latter is more frequent in the blogosphere. Fake blogs unjustifiably extract text from other sources on the Web and publish them as a post, and are only created for search engine spamming. They create favorable relevance to posts on diverse topics, enabling placement of context-sensitive advertisements that drive revenue. The use of fake blogs as a spamming technique is driven by the very nature of blog content and blogging infrastructure.

Blogs are usually commentary oriented, in which an excerpt from another page is included as part of the post. This makes it difficult (for humans and machines alike) to differentiate between fake and authentic blogs, thereby giving splogs credibility they do not deserve. Indeed, further blog hosting services and applications provide programmatic interfaces for posting content, which in turn eases the automated posting of large amounts of spam content. In addition, blog search engines return results by post time stamp, making fake blogs an easy and effective spamming technique. These fake blogs make the splog detection problem particularly challenging. It should be noted here that comment, trackback, and (update) ping spam are different aspects of blog spam, although they might be related to splogs.

The issue of splogs has quickly grown. Research has estimated that one in five blogs is a splog. For example, the tracking service Technorati, which follows 20 million blogs, found that up to 8 percent of the 70,000 blogs created

every day are fake. Feedster blocks thousands a day, while Splogspot.com publishes a weekly list of splogs. The latest figures show 41,000 splogs, of which 34,000 are on Google's free Blogspot hosting service.

Splogs have caused various problems to many Internet users. For example, splogs can clog up search engines, making it difficult to find real content on the subjects that interest users. They may scrape content from other sites on the Web, using other people's writing to make it look as though they have useful information. In addition, if an automated system is creating spam posts at an extremely high rate, it can impact the speed and quality of the service for legitimate users.

Political Effect

Splogs have been an issue in the political arena. In 2008, there were allegations accusing political blogs of being splogs in order to convince Google to block these political blogs. As a result of these allegations, several anti-Obama bloggers were unable to update their sites, which were hosted on Google's Blogger service. These bloggers, most of whom were supporters of Senator Hillary Clinton and opposed to Senator Obama, received a notice from Google claiming that their sites had been identified as potential splogs, and that they were not able to publish any more posts to their blogs until Google reviewed their sites and confirmed that their sites were not spam blogs.

Although Google announced that it had not been tricked, it admitted that the cause of the temporary blockage was because of the antispam filter. According to Google spokesman Adam Kovacevich, Google's antispam filters caused some blogger accounts to be blocked from creating new posts. He mentioned that this may have been caused by mass spam e-mails mentioning the "Just Say No Deal" network of blogs, which in turn caused Google's system to classify the blog addresses mentioned in the e-mails as spam. He insisted that Google restore posting rights to the affected blogs as soon as the incident had been investigated, and stressed that Blogger remains a tool for political debate and free expression.

Sponsored Listings

Sponsored listings (also known as sponsored links, sponsored search, or sponsored ads) refer to a set of online search-based advertisement schemes, advertisements that are based on users' queries on a search engine and are guised as organic results. Unlike advertisements in traditional media, sponsored listings are more organically integrated into the naturally occurring practices of users' online behavior. They appear as a result of a query made by users. For example, a user looking for information on a medical condition is likely to have products and services pertinent to that condition appear as results, which are ads. Surveys report that only a minority of search engine users is aware of the distinction between sponsored and organic search results, and still a smaller minority can tell the difference between the two.

Providers of sponsored listings are primarily search engines and social networking sites. These media do not only provide advertisement space, but also act as technologies that collect real-time information from the audience, indicating the kind of ads that an audience will respond to. The companies profiting most from sponsored listings are Google (almost all revenues come from

search-based advertising) and Bing, the biggest search engines.

Sponsored listings work as follows: An advertiser bids for keywords with a search engine company. Once a user makes a query using that keyword, the advertisements that won the bid are displayed as part of the result page. Bids are dynamic, and respond to basic market rules of supply and demand. The most expensive keywords in Google Adwords (the company's sponsored listings program) in 2011 were insurance, gas/electricity, mortgage, attorney, claim, loans, and lawyer. Winning biddings for each reached dozens of dollars.

Unlike traditional marketing, which segments customers based on demographics and past behavior, sponsored listings rely on the dynamic interests of consumers, which segment themselves to an individual level. The technology can help advertisers determine not only which keyword to bid on, but also which demographic the ad would target. For example, a cooking Web site can bid on the keyword *cheesecake* in a search engine, and can limit its display by geographical and temporal specifications (geotargeting and temporal targeting, respectively).

Unlike traditional advertising, advertisers pay not for impressions (i.e., how many potential consumers watched the ad), but for clicks, those consumers who were interested enough in the ad to follow its link, a method commonly known as pay per click (PPC). This innovative model is made possible by the interactive nature of new media, where the effectiveness of the ad can be measured in real time in terms of visibility and its ability to drive action.

One of the most recent developments of sponsored listings is Facebook's Sponsored Stories, introduced in 2011. Sponsored Stories allows companies to buy posts by users pertinent to their business, and feature them as advertisements in the news feed of these users' friends. It features all the key elements of sponsored listings: their organic nature and reliance on audience labor, and the capacity of these media to access individualized information in real time and commodify it. Indeed, almost all global businesses report using social media marketing.

A more critical outlook suggests that sponsored listings represent a mixture of advertisements

and organic search results, or the commodification of personal information. They epitomize the Internet as an entangled space where information is free and accessible, but also has an economic value and is highly commodified. This undermines the ideological view of search engines as a neutral, unbiased medium between users and the plethora of information on the Web. Search results reflect not only the interests of users to get the most relevant results, but also commercial interests.

In business discourse, sponsored listings are portrayed as a way by which powerful and indispensable search engines can be provided for free. A more critical political economy analysis, however, sees the free service as a form of wages for audience labor. Users of search engines produce a plethora of valuable information, commodified and sold by search engine companies to advertisers. This information concerns users' geolocation, consumerist behavior, and general interests. Indeed, in comparison with mass media, advertisements on social media are conditioned on audience labor to a greater extent.

Conclusion

In sum, sponsored listings are a form of advertising that builds on the sociotechnical features of Web 2.0—particularly its interactive and networked nature, its capacity to activate audiences, and its ability to mobilize audience labor both at the aggregate and individual levels. Sponsored stories epitomize important tensions that prevail on the Internet between free, collaborative culture on the one hand, and commodification on the other hand.

Stanford Center for Internet and Society

Founded at the Stanford Law School in 2000 by Lawrence Lessig, the Center for Internet and Society (CIS) serves as a public interest technology law and policy program. As part of Stanford Law School's Law, Science and Technology Program, the CIS aims to examine how new technologies and the law intermingle, interrelate, and interconnect in ways that promote or hinder a variety of public goods. The public goods that interact with technology and the law and that are explored by the CIS include diversity, free speech, innovation and invention, public commons, privacy, and scientific inquiry. The CIS undertakes a variety of programs to address these issues including publications, symposia, and statements on matters of topical concern.

The Stanford Law School, due in part to its proximity to a variety of high-technology firms, including those involved in the manufacture of computer hardware, software, and other related businesses ("Silicon Valley"), has long had an interest in areas related to the Internet and how it affects individuals and society. Lessig, then a faculty member at Stanford Law School, founded CIS in an effort to focus attention upon an area of increasing importance to those interested in civil rights, free expression, and technology. The CIS joined other Stanford Law School centers devoted to a variety of themes including international law, natural resources and the environment, conflict resolution, corporate governance, negotiation and mediation, criminal law, and computers and the law.

As a former law clerk for both Judge Richard Posner of the U.S. Court of Appeals for the Seventh Circuit and Justice Antonin Scalia of the U.S. Supreme Court, Lessig was well versed in the law and economics approach favored by both of those

jurists. Lessig, now Roy L. Furman Professor of Law and Leadership at Harvard Law School, is known for his interest in copyright and trademark law, especially as it pertains to use with technology. Lessig based the CIS in part upon the objectives of the Berkman Center for Internet and Society at Harvard, a research and advocacy center that examines issues related to the World Wide Web. In particular, Lessig has advocated reducing the limitations on copyrighted and trademarked material, and has also opposed legislation extending these protections. Although Lessig left Stanford Law School in 2009, the CIS continues to advocate for these positions.

Areas of Interest

Although interested in most interactions involving the Internet and society, the CIS concentrates on four areas. These four areas include architecture and public policy, copyright and fair use, privacy, and robotics. Examining how changes in computer network architecture shape the economic environment for those seeking to create new applications and foster competition on the Internet, the CIS also considers how the law will respond to these transformations. Recognizing the constitutional bases of the United States' copyright system, and the significant financial encouragement such protections provide, the CIS also seeks to protect fair use, which safeguards vital public interests such as free speech and expression. Using the many perspectives afforded by Stanford University's disciplinary strengths, the CIS has delved into how privacy is defined in the 21st century, especially as it interacts with new technologies. Finally, the CIS has investigated how administrative law, personal injury proceedings, malpractice suits, and employment regulations are affected by the increasing use of robotics in manufacturing, warehouses, health care facilities, and schools.

Projects

As it provides leadership in investigating and exploring these pressing policy issues, the CIS works to engage decision makers to consider democratic values and civil rights when crafting guidelines and procedures that relate to these issues. To this end, the CIS creates educational resources and studies that further explore matters that involve civil rights, free expression,

and technology. Sponsoring a variety of conferences, symposia, and workshops, the CIS seeks to provide speakers on these issues to a variety of audiences so that attention will be paid to these important concerns.

The CIS also sponsors the Fair Use Project, which serves as a legal clinic and provides representation to clients involved in litigation involving copyright and trademark matters, free speech, technology, and civil rights. The Fair Use Project has assisted individuals seeking to use or make reference to material that is copyrighted through assertions that the fair use exception to the copyright law should be broadly interpreted so as to permit use of material for commentary, criticism, library annals, reporting, research, teaching, scholarship, and search engines.

Although not always successful, the Fair Use Project has permitted litigants the resources necessary to withstand legal challenges from movie studios, record companies, publishing houses, and broadcasters who tend to have deep pockets that permit them to engage in legal skirmishes that are tactically intended to intimidate individuals and small businesses.

Barbara van Schewick succeeded Lessig as CIS faculty director, and she is joined by other directors responsible for copyright and fair use, civil liberties, and privacy projects. The CIS has worked to provide materials and position papers related to emerging issues related to technology and society. For example, the CIS has recently sponsored publications regarding the practices involved in hydraulic fracturing (fracking) used to remove petroleum products from the Earth, law enforcement procedures and privacy considerations related to unmanned aerial vehicles (drones), protecting worker rights related to the Computer Fraud and Abuse Act (CFAA) that permits employers and law enforcement agencies to classify workplace behavior as a federal crime if it involves a computer, and other emerging areas of concern. As technology evolves and becomes increasingly important in a variety of aspects of individual's lives, the work of organizations such as the CIS will continue to be relevant and important.

Streaming Media

Before broadband Internet was widely available, it took a long time to download large multimedia files and view them. To compensate for this, streaming media was developed. When the connection was slow, the browser, plug-in, or application could start displaying the content without waiting for the download to complete. Currently, this is part of cloud computing, where all data is stored in the cloud, as is the case with multimedia content. The ability to stream material on the Web and over social media conduits is increasingly important in the political sphere because both candidates and advocacy groups have come to rely on these technologies to ever-greater extents.

Streaming media currently refers to all multimedia streaming content on the Internet. While delivered by the host, streaming media is, hence, multimedia that is continuously downloaded by, and immediately shown to the user. An application plays the data that is presented by the host before the file is entirely downloaded. Streaming media may not only refer to the most common examples, such as video and audio. Other live media, such as stock exchange data, closed captioning, and Twitter feeds can be considered streaming media. Of course, audio and video can also be presented live or in real-time via

the Internet. Web radio channels and television broadcasts make use of this option.

The first type of streaming media was Muzak. Inventor George Squier was granted patents for a system for the transmission and distribution of signals over electrical lines in the early 1920s. In the 1930s, this led to Muzak, which entailed continuously streaming music to commercial customers without the use of a radio.

It took until the 1990s before enough progress was made in hardware capabilities to display streaming media on computers. In the 1970s and 1980s, high cost and limited capabilities prevented the breakthrough of personal computer systems to the mass market. Nonstreaming media included digital file storage systems such as floppy disks, CD-ROMs, and tape media.

Only in the 1990s did personal computers become affordable and powerful enough to support the required CPU power and bus bandwidth to bear up to the required data and content rates from the Internet to prevent interrupted media playback, and buffer underrun. In the past 15 years, Internet users have encountered bigger network bandwidths, better networks, and increased connectivity and standardized protocols and formats, such as TCP/IP, HTTP, and HTML to enhance streaming media's possibilities. Most of the biggest social networking sites and media platforms, such as Twitter, YouTube, Spotify, and Facebook, all support or even deliver streaming media in the form of video, audio, and text.

Advances in networking capabilities and affordable hardware have made streaming media almost ubiquitous, especially with regard to mobile Internet. Smartphones, tablets, radio devices, televisions, and even photo and video cameras not only support the playback of streaming media via (mobile) wireless connections, but most of the technologies also support recording, uploading, and, optionally, live-stream multimedia. While media files became bigger because of consumer demand for high-definition video and audio, this also led to better and more complex compression of media files and more storage and transmission capacities.

Streaming media is frequently found as either live streams or video on demand. Live streams allow users to view and broadcast live video content using a camera and a computer. Examples of

content include Web casts, live sports events, and news broadcasts. Platforms supporting this functionality include TwitVid, BlogTV, Justin.tv, and Ustream.tv. The latter, video on demand, is a system that allows users to select content on demand and watch it. A set-top box, a computer, or any other device, such as a smartphone or tablet, allows the user to stream the content, in real time.

Streisand Effect

The attempted suppression of embarrassing, harmful, or otherwise private information can have the unintended outcome of increasing its visibility. This frequently occurs with legal action aimed at quieting inconvenient content or critics that generates publicity. The Streisand effect captures this loss of information control, which is facilitated by more highly distributed communication networks. The inspiration for this eponymous term dates back to 2003. The American vocalist star Barbra Streisand sought to remove an aerial photo of her California estate from the California Coastal Records Project. The nonprofit project maintained an online collection of 12,000 photos of California's coast in order to document erosion and promote environmental awareness. Streisand

felt that the image invaded her privacy. Her action and then lawsuit against the project's photographer, Ken Adelman, attracted wide media coverage. The photo of her house circulated, and this image arguably received far more publicity than it would have if Streisand had taken no public action. Streisand lost the case, Adelman successfully countersued, and the photo is still available on the project's Web site.

Mike Masnick coined the term in a January 2005 Techdirt blog post. Writing critically about an airport and a resort that sought to suppress their mentions in a Web site dedicated to photos of public urinals, he observed that the result was similar to Streisand's legal campaign. Masnick wrote that lawyers had to understand that seeking to remove online content can easily backfire. At the end of the post, he declared: "Let's call it the Streisand Effect." Over the years, the concept has gained more currency among academics, pundits, and mainstream media who see traditional information-suppression methods as counterproductive.

Examples

Despite the lesson of this effect, subsequent examples of secrecy that only generates further attention abound. One commonly cited case involves the Church of Scientology's attempt to have a video of Tom Cruise taken offline in 2008. Many more viewed the video after hacker groups like Anonymous and the news media talked about it, and it was posted on numerous Web sites. Also, the U.S. government's campaign to block the availability of WikiLeaks's published State Department diplomatic cables piqued global interest.

In April 2013, the French domestic spy agency Direction Centrale du Renseignement Intérieur (DCRI) forced Wikimedia France to take down an article containing allegedly classified information about Pierre-sur-Haute, a military radio base. After Wikimedia France publicized this in a press release, the story spread around the world. The reposted article was soon translated and further disseminated internationally, becoming the highest viewed page on Wikipedia's French page.

Role of Information Technology

While lawyers and governments have long considered the risks of adverse publicity accompanying litigation or prosecution, the Streisand effect

Contrary to Barbra Streisand's intent when she fought for the removal of an aerial photo of her California estate taken by the California Coastal Records Project, the lawsuit led to extensive media coverage and the coining of a phrase in her name.

involves the more rapid circulation of news and multimedia content. Enabled by the wider distribution of digital publication and content-sharing capabilities—from blogging platforms to social media—the Streisand Effect most often refers to instances by which computer-mediated communication is central. Information technology is central for two reasons. First, with the greater circulation of data, private individuals, organizations, companies, and governments are more likely to find objectionable content, giving them more cause to seek content removal. Second, a more dynamic and complex information environment increases the likelihood that legal endeavors to quiet someone will attract wider publicity. Defendants and issue advocates can more easily “go public,” that is, publicize the suppression efforts.

The Legal Context

The Streisand effect is not just caused by changes in technology but draws on dimensions of the legal system. In the American context, the high levels of litigiousness around information has a history, while the rules and conventions of public access to the courts help enable public attention to lawsuits.

In the United States, private legal action to quell public criticism is frequent enough to be given an acronym. A SLAPP suit, or a strategic lawsuit against public participation, is designed

to pressure critics into silence through the threat of expensive litigation, even if the grounds for the suit are dubious. Those seeking the removal of content frequently start with a cease-and-desist letter. It outlines the potential legal violation and suggests actions that the letter's recipient can undertake to avoid penalties or costly litigation. Use of SLAPP suits and cease-and-desist letters increased in the earliest days of Web publishing.

Previously, someone subjected to a SLAPP suit or a cease-and-desist letter who lacked resources to expend on legal representation did not have much recourse, and as such, tended to comply. (Anti-SLAPP statutes have been passed in some states, however. These encourage countersuits against SLAPPs.) However, the same tools of Web publishing can be used to publicize such letters. The photographer who Streisand sued countered by publishing the letters and legal documents. Going public could both scrutinize those seeking to remove content and help a potential defendant to gain access to crowdsourced legal advice.

Public access to courts is well established, rooted in the constitutional right to a public trial, and has become conventional, even though openness is not absolute. This also fuels the effect. Those interesting in writing and commenting on an unfolding court case can draw on legal documents and sit in on proceedings.

Movements and Organizations

There is a freedom of information community that promotes increased public access to knowledge and opposes efforts to enhance secrecy. They are instrumental to highlighting legal efforts contrary to the spirit of openness. For example, they take exception to government efforts to restrict the public's access to government documents and proceedings. They draw attention to overt government steps to restrict information access.

Organizations dedicated to publicizing efforts to remove online content have also emerged. The Chilling Effects Clearinghouse, for example, was founded at the Berkman Center for Internet and Society. It gathers complaints and cease-and-desist letters to enhance the publicity costs of unwarranted measures to silence speech. Social movements and issue advocacy groups can also promote information that the government or their opposition seeks to quiet.

Political Implications

The Streisand effect matters politically to the extent that incumbent powers, governments, corporations, and famous individuals have less latitude to prevent public criticism through prior constraint, censorship, or lawsuits. It shows that previous instruments of controlling information are outmoded. Over the long term, it may prove more valuable to simply ignore criticism, given the problem of information overload. Similarly, some could flood the public with countervailing messages to cause confusion. Or, powers could seek changes to the law to allow for more secrecy around attempts at suppression, thereby solving the paradox of the Streisand effect.

Strong-Tie Social Connections Versus Weak-Tie Social Connections

Discussions regarding the strength of social ties relate to social capital theory. As Robert Putnam describes it, social capital theory suggests that social networks have value at the micro

(individual), meso (community), and macro (societal) levels. An individual's social network is comprised of multiple, multiplex social ties of varying strengths. Strong ties exist among individuals connected within densely knit, homogeneous networks such as those involving kin and close friends. Weak ties exist among individuals connected within sparse, heterogeneous networks such as those involving acquaintances.

Strong and weak ties, according to Mark Granovetter, are both important because they connect individuals to valuable resources (e.g., information or opportunities). The utility of strong and weak ties varies, however, as a function of the particular situational context in which it is utilized. The different utility of strong and weak has been widely debated as a result of the implications of tie strength for a wide variety of social and psychological outcomes, such as psychological well being, social capital and cohesion, job opportunities and social mobility, and political and civic engagement. This debate has been amplified by the emergence and influence of new technology, especially social media.

Strong Versus Weak Ties

As Granovetter posits, the strength of any tie is a function of the frequency and duration of interaction, level of emotional intensity and intimacy, and the reciprocal services found within the tie. On a continuum, strong ties involve more frequent interaction, emotional intensity and intimacy, and feelings of reciprocity. Strong ties are often homophilous in nature. That is, they form among individuals who share similar cultural, demographic, or attitudinal characteristics. According to Granovetter, the stronger the tie, the more homophilous the tie. This relationship results in a densely knit, exclusive social network where those connected via strong ties also share other friends—friendship circles tend to overlap.

Weak ties exist on the opposite end of the continuum. Weak ties involve less frequent interaction, lower levels of emotional intensity and intimacy, and lower feelings of reciprocity. Moreover weak ties are less homophilous than strong ties. That is, they form among individuals who share varied cultural, demographic, or attitudinal characteristics. Consequently, weak ties represent a relatively heterogeneous, sparsely knit social

network. This relationship results in a sparsely knit, inclusive social network where those connected via weak ties rarely share other friends—friendship circles tend to remain distinct.

The Strength of Strong Ties

Historical comparisons of strong and weak ties have typically concluded strong ties connect individuals to be more beneficial social and psychological resources than weak ties. Their “bonding” function has been especially heralded. That is, strong ties strengthen interpersonal relationships, resulting in increased feelings of reciprocity and trust. This cultivates feelings of social solidarity and overall social cohesion. From this perspective, strong ties reflect Ferdinand Tönnie’s conceptualization of *Gemeinschaft*—a geographically bound community characterized by a strong sense of togetherness and moral obligation. This generates greater motivation to provide assistance to strong ties during times of need. For example, it is often easier to convince family and friends to help one move across town than it is to convince an acquaintance to help.

Because of their distinct characteristics also strong ties can possess certain negative aspects. As Putnam suggests, strong ties can result in antisocial outcomes such as sectarianism, ethnocentrism, and corruption. They can also cultivate exclusive identities and a narrow sense of self. Granovetter also suggests that although strong ties breed local cohesion, they do so at the expense of the exchange of opportunities and information with diverse others. Their insular and exclusionary nature, therefore, contributes to social isolation and the overall fragmentation of society.

The Strength of Weak Ties

Weak ties can also be utilized to connect individuals to valuable resources. Granovetter is a strong advocate for the “strength of weak ties,” suggesting that they serve an important “bridging” function. That is, weak ties foster connections across cliques or subgroups, opening paths for the rapid and efficient exchange of opportunities and information across social distance. Granovetter suggests that certain weak ties represent “local bridges”—the most efficient links between social groups because they minimize the

amount of time, energy, and potential for message distortion. Weak ties connect heterogeneous individuals to valuable resources unavailable within the densely knit, exclusionary structure of one’s close ties. And while all weak ties are not necessarily bridges, strong ties, by definition, cannot serve a bridging function. Such interaction and sharing across heterogeneous weak ties can therefore be viewed as contributing to social integration and cohesion.

Historical and contemporary critiques of weak ties originate from the belief that they lack the feelings of reciprocity and trust characteristic of strong ties. From this perspective, weak ties mirror Tönnie’s conceptualization of *Gesellschaft*—a community comprised of fluid, contractual, and instrumental relationships based on individual self-interest—and cultivates individualism and feelings of social alienation.

The Changing Nature of Social Ties

Concerns about the balance of strong to weak ties within individuals’ social networks have existed since the Industrial Revolution. These concerns originated as a result of urbanization, improvements to transportation and communication networks and technology, and the emergence of consumer culture, among other factors. As Barry Wellman has documented, these changes have initiated a social shift from what he terms “neighborhood-based communities” to “person-to-person” communities. Geographically bound, densely knit communities of strong ties have not been replaced, but are rather supplemented by “far-flung, loosely-bounded, sparsely-knit and fragmentary” communities comprised of self-selected strong and weak ties. Individuals actively create communities of kin, neighbors, friends, coworkers, and various other acquaintances who share interests.

The emergence of “person-to-person” communities has been met with some trepidation. Critics fear that these communities of “limited liability” lack the same sense of reciprocity and trust present among strong ties. They fear consequences such as diminished face-to-face interaction, increased feelings of alienation, lower levels of social cohesion, and diminished life satisfaction. Yet, far from signaling a definitive shift from *Gemeinschaft* to *Gesellschaft*, Wellman argues that new

forms of community coexist with and supplement pre-existing modes, much like strong and weak ties coexist and supplement one another.

Tie Strength and Social Media

Initial analyses of the effect of social media on tie strength echoed concerns previously raised. Critics bemoaned the geographically dispersed, anonymous, and voluntary nature of social ties predicated on shared interests. The integration of social media into daily life only amplified concerns regarding diminished opportunities for face-to-face interaction. The technological features of social media (e.g., enabling both synchronous and asynchronous interaction) also raised concerns regarding its ability to convey emotion and cultivate feelings of reciprocity and trust. Essentially, critiques concluded that ties created and maintained online via social media were less supportive and beneficial than those created and maintained offline.

Current thinking, however, presents a more balanced view. Studies of social media, specifically social networking sites (SNSs) such as Facebook, conclude that SNSs support sociability and quality social ties in a similar fashion to face-to-face and geographically based social interactions. Such findings emerge from the fact that SNSs are more often used for tie maintenance, rather than creation. That is, individuals rely on SNSs to maintain existing offline ties, rather than creating connections with anonymous, online others. Often, online interaction fosters offline interaction, such as when friends coordinate face-to-face meetings via social media. SNS “friends” are therefore more likely to include family members, close friends, coworkers, and old high school friends than individuals who share some interest, but had not met offline prior to “friending” one another. Caroline Haythornthwaite has posited that many SNS-based ties may not actually exist without SNSs. These “latent ties”—ties that remain meaningful but suffer from a lack of frequent interaction—can actually be strengthened as a result of social media-based interaction. That is, interaction via social media holds the potential to improve tie strength by converting latent ties into weak ties and weak ties into strong(er) ties.

Malcolm Gladwell and Clay Shirky’s debate regarding the role of social media and tie strength

in contemporary political activism reflects these divergent perspectives. Gladwell argues that social media are a weak-tie phenomenon capable of increasing participation in social causes by facilitating collaboration, coordination, and the expression of ideas. However, it does so by decreasing the level of financial or personal risk involved in participation. According to Gladwell, high-risk activism is a strong-tie phenomenon, and therefore is absent in social media activism.

Shirky argues that social media is integral in high-risk activism, irrespective of the strength of ties present within a network. As he argues, social media strategies connect committed social actors and create new strategies and bonds that facilitate social change. Specifically, social media increase access to information and the ability to respond to information on a massive and rapid scale, which helps actors coordinate and demand social change. Shirky acknowledges that superficial social media activism exists, but concludes based on anecdotal evidence from recent social movements that social media represents a vital tool capable of strengthening civil society and the public sphere in the long term.

Implications of Tie Strength

In the absence of empirical evidence, the Gladwell and Shirky debate remains unresolved, but illustrates that the composition of social networks and the integration of social media into their maintenance and functioning has numerous implications for political and civic life. As Putnam proposes, for a democracy to properly function social capital must be managed to maximize the positive consequences while minimizing the negative consequences. This logic holds, regardless of whether democratic discourse and functions occur offline or online.

Tie strength, for instance, influences the likelihood and nature of political discussion and civic deliberation. It is more likely to occur among close ties, but discourse may be limited to topics relevant and/or acceptable within the local community. Close ties may also exert undue social pressure to conform one’s thinking to the group norm, or to adopt more extreme views than under other circumstances. Weak ties play an opposite role in this process. Such discourse may occur less among weak ties, but more diverse perspectives

and inclusive worldviews can result instead in partisanship, polarization, and political bickering.

Active political discussion and civic deliberation contributes to social cohesion and the formulation of a local identity and political and civic participation. This may manifest itself as a commitment to a community, or through involvement in community organizations. The rise of “person-to-person” communities complicates this relationship, because increased connections to weak ties may shift one’s primary local identity and engagement from geographically bound communities to geographically dispersed communities.

Strong ties, especially those that are geographically proximal and benefit from frequent interaction, may be more easily mobilized to achieve collective goals than geographically dispersed weak ties. However, when social networks are comprised of too many strong ties, it becomes less effective at mobilizing individuals outside of the close ties to their cause. Hence, it becomes necessary to mobilize both strong and weak ties to achieve desired individual and communal ends within and across communities.

Conclusion

Current thinking concludes that tie strength is not indicative of more or less beneficial social ties. Both are capable of promoting political and civic participation because they help individuals gain relevant information, create meaningful interpersonal relationships, and coordinate to achieve individual and collective goals. But it is only through the combined resources made accessible via both strong and weak ties, complete with their ability to provide bonding and bridging social capital, that individuals, communities, and society at large gain the resources needed to fully and efficiently participate in a democratic society. Social media supplements, rather than detract from, this process.

StumbleUpon

StumbleUpon calls itself “a discovery engine that finds and recommends Web content to its users.” In fact, it is a Web search engine that allow users to discover and rate Web pages, Facebook posts, Twitter updates, photos, videos, and all other Web content that is personalized to their tastes and interests using peer-sourcing and social-networking principles. To monitor a users’ browsing, toolbar versions of the service are available for all major browsers and mobile operating systems. Founded in 2001, StumbleUpon had 1 million users by December 2002. In 2012, the Web service claimed 25 million registered users.

Technology and Derivatives

Web 2.0, the current phase of the World Wide Web and online applications, is characterized by interactive and dynamic content. Web 3.0 is assumed to comprise the following opportunities: a hybrid, semantic, and intelligent Web made possible by the convergence of several new technologies, which will make data and content more usable and accessible. When the World Wide Web changed from 1.0 to 2.0 to 3.0, the user changed, respectively, from a viewer, to a producer/prosumer,

to a producer and user of personalized content. This personalized content is both user generated and machine generated. It offers many new possibilities to the user because it makes content more accessible and usable with recommendations or a (machine-) predefined selection of content.

StumbleUpon answers to this possible semantic, intelligent Web and uses collaborative filtering where machine-generated and user-generated content are also combined. This comprises the combination of human opinions with machine learning of personal preference, which makes it possible to recommend new Web sites to like-minded Internet users. The common interest is found by monitoring the surfing behavior of users and collecting explicit interest information, such as “likes” or other ratings. In combination with the social network, the service offers pages to “stumble upon,” explicitly recommended by friends and peers. Other options included in the service are creating favorites and stumble personal interests that are not reflected by the user’s social network.

The StumbleUpon toolbar makes it possible to give a site a “thumbs up” or a “thumbs down” and to write commentary. StumbleUpon tries to recreate a “word-of-mouth” referral of Web sites, and as with Web 3.0, should improve the Internet experience by recommendation and personalization. Other features of the service include content filters, allowing the user to stumble with audio, video, or images, and a personal overview page.

In 2006, StumbleUpon launched StumbleVideo. The site aggregates videos from CollegeHumor, DailyMotion, FunnyOrDie, Google, MetaCafe, Myspace, Vimeo, and YouTube, and allows users to stumble through all these videos.

The StumbleThru service was launched in 2007. The service allows users of the toolbar to stumble within sites such as YouTube, WordPress, *Rolling Stone*, Wikipedia, and many others. StumbleThru focuses on specific sites, rather than the entire Web. In 2009, StumbleUpon launched Su.pr as its own URL-shortening service comparable to TinyUrl,youtu.be, or bit.ly. It is primarily used to link to Twitter and Facebook statuses and updates.

Business Model

As with most social networking Web sites and Internet services, StumbleUpon’s free service uses

advertising income to generate money. The ad system it uses to improve the ad experience is called Paid Discovery. The hybrid of machine-generated and user-generated content is embedded to create a better user experience, matching one’s personal interests. Paid Discovery also uses the same hybrid to include an advertiser’s URLs (Web sites, images, and videos) and make them part of that stream.

Up to 5 percent of all stumbles are reserved for Paid Discovery, where advertisers directly insert their Web page into the user’s experience. This means that the audience lands directly on their Web pages, videos, and photos. Users can also provide feedback (“thumbs up” or “thumbs down”) on this content. Different from other Web services, no pop-ups, advertisements, or banners are displayed because Paid Discovery sends visitors directly to an advertiser’s page. To indicate this feature, “Sponsored” is shown in the toolbar or mobile app.

Sunlight Foundation

The Sunlight Foundation is a nonprofit organization that focuses on improving the transparency of government in the United States. It is nonpartisan and specializes in putting information that

is publicly available online and in making that information more useful by creating Web and mobile phone tools and applications, along with promoting changes to government policy that encourage greater openness of information. It was founded in 2006 by the well-respected and well-connected lawyer Michael Klein, and Washington, D.C., advocacy expert and activist Ellen Miller. This dual expertise in law and grassroots public activism is reflected throughout the organization's history, current issue area focuses, and information tool development.

History

Since 2006, the Sunlight Foundation has been at the center of a number of high-profile campaigns that both respond to political events as they occur, and which seek to shape the future accessibility of government information. Most of its past projects continue in some form, but it has also been part of major political stories in its own right. These include exposing political conflicts of interest and inaccurate financial disclosures, and crucially, working with the U.S. Congress and other groups in a collaborative effort known as the Open House Project. This early work brought in congressional workers from Capitol Hill, lobbyists, grassroots activists, and information specialists to craft recommendations on how the U.S. House of Representatives could make more of its process and data publicly accessible, and generated a report that was presented to the House to generally positive reviews in 2007. This work has been complemented by a number of similar efforts that use technology to reveal the influence of money in politics, the way in which bills evolve through the legislative process, and the use of earmarking by politicians to gain special favors and funds for constituents and contributors.

Issue Areas and Projects

The Sunlight Foundation identifies two primary issue areas, each with additional subtopics as their priority concerns. The first is the “transparency of money in politics,” and the second is “opening government data.” Each of these areas is targeted through data tool creation, lobbying, and public awareness campaigns.

The money in politics concern is currently split into eight active campaigns. These include efforts

about campaign contributions in advocacy of the Disclose Act, a campaign finance reform bill that requires much greater disclosure of funding sources for politically active organizations, an exploration of the *Citizens United* Supreme Court decision and a look at its implications for fiscal transparency and access, and an examination of the links between the finance industry and government officials.

Other projects in this advocacy area focus more on the lawmaking process, with tools for seeing what earmarks lawmakers have added to given bills, an examination of food and health policy and what actors are influencing them, and reports on lobbying activities and work on making those reports available in real time instead of a considerable amount of time after events and meetings have occurred.

Two other ambitious projects include an effort to make all television political ad records publicly available, which would allow people to know who is paying for various ads and who is providing them for distribution, and a continuation of the Open House Project called the Senate Campaign Disclosure Parity Act, which would make it mandatory for Senate campaign financial reports to be filed electronically.

John Wonderlich, left, policy director of the Sunlight Foundation, gives a presentation on freedom of information at the Open Up! “Show and Tell” gallery tour in London on November 13, 2012.

The opening government data concern is a more ambitious effort, but is split into only four categories. The first is a position that papers published by the Congressional Research Service, which is the nonpartisan service that crunches the numbers and finds the data that representatives and senators need to make decisions on legislation, should be made publicly available and easily accessible, rather than needing to be specifically requested from a legislator. The Sunlight Foundation has published editorials in prominent newspapers, published posts on the issue on its blog, and has begun the process for Congress by helping to fund Open CRS, which is a database of many significant CRS reports.

Sunlight also has an effort called Freeing Federal Data, which seeks to augment White House open data executive orders and databases like Data.gov with an important added level of disclosure, namely, how the government decides which information to release. This allows for information to remain secret if necessary, but also provides a public rationale for doing so, and a standard by which political actors can be held accountable.

The third key area of opening data focuses on the state legislature level of government, which is often overlooked, but is equally influential on day-to-day life. Specifically it looks at how model legislation is prewritten by interest groups, and then lobbied to various state houses. Its Superfast-match tool identifies shared wording and phrasing across pieces of similar legislation from different states, sometimes revealing that lawmakers have simply copied and pasted language directly from interest groups.

Examples of this effort's effectiveness include the exposure of the NRA's provision of language in "stand your ground" laws, and the role of the American Legislative Exchange Council (ALEC), a group composed of exceptionally wealthy companies and individuals in a host of regulatory legislation. Finally, National Data Apps use federal information to provide useful information to the public on health care and quality of life through simple mobile applications.

Applications

Sunlight's present Web and mobile applications are its primary entry into public discourse. Prominent among these are Churnalism, which identifies

the repackaging of press releases as news reporting; Checking Influence, which shows how retail firms engage politically; Influence Explorer and Poligrift, which connect political contributions to relevant legislation; and Scout, which is an online alert service that allows users to receive instant updates on legislation and issues when they are acted upon by Congress. In sum, these efforts have produced a wealth of tangible data, and have greatly improved the accessibility and usefulness of federal data on behalf of U.S. citizens.

Superconnected

A widely accepted understanding of the term *superconnected* originated in a September 1997 survey by *Wired Magazine* and the Merrill Lynch Forum. Based on the analysis of several surveys, the authors "divided those polled into four groups: the superconnected, who exchanged e-mail at least three times per week and used a cell phone, a beeper, a laptop, and a home computer; the connected, who exchanged e-mail at least three times

per week and used three of the four technologies above; the semiconnected, who used at least one but not more than four of the target technologies; and the unconnected, who did not use any of the target technologies.”

Evolution of Telecommunications

Communication is a function inherent to any living organism; humans distinguish themselves from other forms of life by using language, and because of the specificity that language allows them. Moreover, communication cannot exist without media tools. Throughout history, people have used different forms of media. With the rise of the Internet, the increasing ease of connecting people with each other is a social phenomenon that has affected many countries in which there is widespread access to digital technology.

The evolution of telecommunications was at the origin of several other revolutions. First, connection to the Internet via a personal computer allowed users to communicate with more of their peers, and also allowed the development of e-mail systems, videos on demand, and browsers. The second revolution is connected to the creation of social networks, such as Facebook and Twitter. The most recent revolution is the use of mobile technology (e.g., smartphones and tablets), which allows the user to be constantly connected from anywhere. It is estimated that the growth in mobile technology will lead to the existence of 40 billion communicating devices by 2015.

The global network, based on fixed points (nodes) and mobile links, has undergone a major technological and societal transformation. The use of transactional technological objects such as smartphones, to connect to the Web means that the point of connection is no longer fixed from a geographical point of view.

Effects of Superconnection

The permanent connectivity of people and objects, regardless of whether they are real (PC or mobile phone) or virtual (software applications), will have a deep impact on the organizational structure of the various civil societies in the world. Furthermore, the notion of a “network” has also evolved. The possible effects of networks connecting an array of users led to Metcalfe’s law (for Bob Metcalfe, a coinventor

of Ethernet). The law stipulates that “values of a network increase proportionally with the square of the number of its users (n^2),” and can be expressed by the formula:

$$U(n) = [(n-1) n/2].$$

The phenomenon of superconnection means that information and communication technologies allow one to connect with anyone else who is also on these networks, regardless of whether the correspondent is a member of one’s family or group of friends. Moreover, users are able to keep up with world events; they can also send videos, share them with other users, or make real-time comments on blogs, forums, or online newspapers. Finally, for the superconnected user, it is less a phenomenon of perception that is activated by digital society, than a mental representation of the objects of the world. This means that the only things that appear real are one’s subjective impressions and thoughts and sensations (solipsism). Indeed, the Internet user understands the virtual object presented on the screen of his or her computer, touchpad, or mobile phone only by seeing or listening; the sensation of touch is excluded because the object represented on a screen is only a manifestation of binary codes.

SurveyMonkey

SurveyMonkey is the world's largest survey company, founded in 1999. The company is helping customers collect over 2.2 million online survey responses every day, and the Web site sees 43 million surveys completed every month. The intuitive Web interface makes it easy for even nontechnical people to create surveys and export collected data. SurveyMonkey works according to the "freemium" principle. On one hand, the Web site offers a free limited account, where one can create an online survey and store a maximum of 100 responses. On the other hand, it offers several premium services on a paid basis, where one can create unlimited surveys with an unlimited number of questions and responses.

The large set of features and services offered, combined with the ease of use of the interface and its pricing structure, are believed to account for the popularity of SurveyMonkey. This article will elaborate on the different features offered by SurveyMonkey and discuss the importance of SurveyMonkey as one of the research tools of the digital era in the case study of the *Slate*/SurveyMonkey Political Survey.

Concerning survey design, SurveyMonkey offers the standard question types such as multiple choice, rating, comment, question matrix, skip pattern, and branching, as well as custom questions. One can add questions that require an answer before allowing respondents to move on to the next question. The service also offers sample surveys and stock questions.

Concerning analysis, the Web site offers real-time results, but also text analysis, SPSS integration, and multiple custom reports, with output files ranging from PDF to XLS and CSV. The analysis tools are able to filter and cross tabulate responses by custom criteria, and the user may create and download custom charts. Several options of both survey design and analysis are limited to paid plans.

The *Slate*/SurveyMonkey Political Survey
Slate, an online daily magazine offering analysis and commentary about politics, news, business, technology, and culture, teamed up with SurveyMonkey to create the *Slate*/SurveyMonkey Political Survey during the presidential election of

2012. On a monthly basis, this survey unveiled "an informal survey of people's attitudes toward the presidential candidates—and how they are shifting." The collaboration featured a survey of more than 1,000 registered voters across the country, drawn from SurveyMonkey's pool of more than 2 million survey respondents.

Despite the fact that the *Slate*/SurveyMonkey Political Graph took a humorous approach to the presidents, it showed the added value of online survey tools for constituency profiling and campaign design research. According to *Slate*, "forging a personal connection with voters is critical. Both camps are trying to present their candidate as someone who connects with voters, someone who is in touch with people's needs. Therefore, we wanted to ask survey participants who they would prefer—Obama or Romney—in basic everyday situations that demand a little bit of trust."

Constituency Profiling and Campaign Design

According to journalist Scott Martin, "online surveys and social-media information have become the de facto research tools of the digital era's fast-moving small businesses." Whereas in the past, surveys required substantial time and money, services such as SurveyMonkey make surveys cheap, quick, and easy to do it yourself online. SurveyMonkey is also used by many political organizations and candidates for constituency profiling and campaign design research. The online survey tools give great options to identify campaign supporters and gather feedback from constituents, but also to gain feedback on political events and speeches. Respondents can be asked to weigh in on political issues and be polled about everything related. SurveyMonkey proves to be an ideal tool for this, in part because they also offer access to possible respondents.

Syria

Following the success of Egypt's January 2011 uprising, a small number of activists called for a "Day of Rage" in Syria on February 5, 2011, using Facebook. While the initial protest was poorly attended, events in early March prompted a wave of protests that quickly spread, setting into motion an uprising that would eventually be described as a civil war. Early protests were well-documented, and the violent images and videos that emerged from them were widely shared on social media and used by journalists. The widespread use of social media in reporting on the conflict resulted in the Syrian government—which already controlled the media and the Internet quite heavily—pursuing online activists through various means, prompting response from hacktivist groups such as Anonymous and leading to what would later be called a full-scale cyberwar among various actors.

Just three days after the initial, unsuccessful "Day of Rage," the Syrian government restored access to Facebook, YouTube, and Blogspot, all of which had been banned since 2007. The response to the action was mixed: While some bloggers

celebrated it, some observers suggested that it would make surveillance by authorities easier to conduct.

Several weeks later, the arrest of several young boys in the southern city of Daraa (reportedly for writing antiregime slogans inspired by Egyptian revolt) triggered local protests, prompting activists to call for a second "Day of Rage" on social media. Scheduled for March 15, the "Day of Rage" attracted hundreds of demonstrators in several cities across Syria, who demanded an end to the country's emergency law, an end to government corruption, and more freedoms.

On March 16, the protests continued in front of the Interior Ministry in Damascus, with an estimated 200 people calling for the release of political prisoners. Several human rights activists were arrested during the protest, prompting calls on Twitter for their release. These events led to the announcement of a "Day of Dignity" on Friday, March 18, a phenomenon that would designate Friday as a weekly day of protest for the first several months of the uprising. On March 18, the first reports of casualties in Syria emerged on Twitter.

Initially, Facebook served as a central location for information sharing, as Syria's Facebook user base quickly grew following the site's unblocking. A page called "Syrian Revolution" that emerged in March 2011 had 41,000 fans within a few days, and by late 2012, had more than 650,000.

As protests in Daraa escalated, graphic videos began to emerge and were posted to YouTube and other video-sharing sites by individuals and citizen media collectives. Some of these groups were formed early in the uprising, such as *Shams News Network*, which states on its Facebook page that it was established February 28, 2011. Citizen videos were used in reporting by media outlets including the *New York Times* (on its Lede blog) by mid-March, drawing global attention to the unfolding crisis. On March 23, news broke on Twitter that 150 demonstrators had been killed in Daraa amid rumors of an Internet shutdown in that city.

By late March, counterdemonstrations began to occur alongside antigovernment ones, with a similar dynamic emerging on social networks. Syria's small but robust blogosphere began to divide along political lines, and progovernment

Syrians organized campaigns on Facebook and Twitter calling for a "Day of Rage" in the capital city of Damascus in February 2011. Inspiration came from Egypt's and Tunisia's use of social networking sites to rally people for sweeping political reforms.

accounts began to emerge in large numbers on Twitter.

Syrians Online

Prior to the 2011 uprising, an estimated 18 percent of Syrians had access to the Internet. The relatively active Syrian blogging community (or "blogosphere") was comprised of a combination of Syrians living in the country and those living outside, with a mix of Arabic and English-language blogs.

Syrians were also users of social media, despite government bans on several sites (including Facebook) put into place in 2007. Many reportedly accessed Facebook by using proxy services. Notably, Blogspot.com—Google's blog service—was blocked, but Blogger.com (the URL at which Blogspot users compose blog entries) was not, allowing Syrians to blog for an external audience.

Unlike Tunisia and Egypt, where social media had long been used for activism, Syrians had only experienced a handful of campaigns. One successful campaign organized on social media occurred in 2009, when groups fed up with the high prices of mobile phone packages organized a boycott of mobile providers, which was picked up by local media and resulted in lowered prices.

An Online Battle

By late March, accounts of government interference with social media began to emerge. One prominent activist, Khaled Elekhetyar, briefly went missing and returned to find government supporters had hijacked his accounts.

In mid-April, a group calling itself the Syrian Electronic Army (SEA) began perpetrating attacks on the Web sites and Facebook pages of those it deemed supportive of the opposition. One example of an early SEA target is the Web site of Syrian singer Asalah Nasri, which was defaced after it was reported by newspapers that Nasri had rejected an invitation to sing in support of Syrian President Bashar Al-Assad.

The SEA also organized spam attacks, whereby hundreds of highly repetitive comments would be left on a selected Facebook pages in a short period of time. The attacks targeted the Facebook pages of those deemed to support the Syrian opposition, including the European Parliament, the White House, French President Nicolas Sarkozy, Oprah Winfrey, and Human Rights Watch.

The SEA's own Facebook page was removed numerous times by Facebook administrators. At one point, the SEA posted a screenshot to its Web site showing an automated e-mail from Facebook explaining that the page was removed for violating the site's terms of use.

Also in mid-April, coordinated spam attacks began to emerge on Twitter. Using hashtags popular with opposition supporters at the time—including #Syria, #Daraa, and #Mar15—the accounts would post messages and links to images, sometimes at a rate of several per minute. The messages and links were typically irrelevant to the conflict, and served the purpose of flooding the hashtags to draw attention away from the opposition content.

In June, President Bashar Al-Assad recognized the SEA as a "real army in virtual reality." While

research by Helmi Noman linked the SEA to the Syrian Computer Society, headed by Assad in the 1990s, direct links between the organization and the government were not proven, and Facebook pages in support of the SEA showed involvement or support from individuals outside of Syria.

The Syrian government had tightly controlled the Internet for years, blocking opposition Web sites, blogs, and social media platforms. In October 2011, the hacktivist collective Telecomix, along with Tunisian group Reflets.info, released a set of logs purportedly showing that commercial network filtering devices produced by the American company Blue Coat were present in Syria. The fact that U.S. sanctions on Syria prohibit the sale of such devices prompted several reports and condemnations, resulting in an investigation by the U.S. Department of Commerce.

Syrian authorities later sought other means to control the flow of information. In February 2012, Syrian activists began to complain of malware attacks, attacks which compromise a computer system, allowing it to be taken over by the perpetrator. Throughout 2012, dozens of such attacks were reported.

Several brief Internet outages were reported throughout 2012, with most presumed to have been perpetrated by the Syrian government. On November 29, 2012, 100 percent of Syria's networks went offline, an outage that lasted nearly 48 hours. The Syrian government blamed the outage on terrorists, but network analysts demonstrated that the networks had to have been shut down from the central backbone.

In response to shutdown, Google and Twitter revived the Speak2Tweet service that had been set up in response to the January 2011 Internet shutdown in Egypt. On Twitter, the hashtag #ThisIsDamascus—an homage to 1956 Syrian broadcasts that kept attention on Egypt when French and British attacks rendered Cairo's radio broadcasts silent—was used to show support for Syrians.

The Gay Girl in Damascus

In June 2011, one story from Syria captured the attention of the world's media. A Syrian American blogger named Amina Arraf, who blogged under the title *Gay Girl in Damascus*, was reported missing on her blog, which was allegedly updated

by a relative. Arraf's alleged arrest was reported by mainstream media, and Twitter users began to call for her release using the hashtag #FreeAmina. A Facebook page was also set up, urging people to contact their local U.S. embassy.

Within days, the story began to unravel, assisted by social media users. NPR journalist Andy Carvin, who had risen to prominence during the Egyptian uprising, used his vast Twitter network to source information about Amina, resulting in further interest from the media. On June 9, the BBC conducted an interview with a woman named Jelena Lecic, who stated that the photos of "Amina" were actually her personal images, stolen from her Facebook account. On June 12, Palestinian blogger Ali Abunimah revealed that "Amina Arraf" was actually the fictional work of Tom MacMaster, an American student living in Scotland. The hoax contributed toward skepticism about other bloggers and citizen reporters in Syria, several of whose identities would later be brought into question.

Media and Verification

Journalists covering Syria from a distance have expressed difficulty in sifting through the abundance of material coming from activists and citizen journalists. Verification is also challenging; following several high-profile errors in attribution (in which the date or location of a video was inaccurately stated by its creators), some media outlets published videos with disclaimers noting that the content's authenticity could not be verified.

One example of journalistic error occurred in May 2011, when Reuters provided television channel France 2 with a video from Lebanon that was presented as originating from Syria. In another high-profile error in May 2012, the BBC presented an image from 2006 in Iraq as having been taken in Houla, the site of a reported massacre. The image, which was removed after nine hours, was captioned "photo from activist."

In September 2011, a revolutionary group posted a video showing the burned and beheaded body of a woman who they stated had been killed by the Syrian government. The family of the alleged victim, Zaynab el Hossni, confirmed her identity, and the video was used in reporting by major foreign media, making Hossni a "symbol of the revolution." Weeks later, however, Hossni

appeared on state TV, claiming that she had fled her home because of abuse.

It has been noted by both observers and activists that some content is intentionally misrepresented by the Syrian opposition in order to gain more attention for its cause. Some activists have admitted to only showing content that fits the narrative of a peaceful revolution.

Amid ongoing conflict, Syrians have used humor on social media to deal with the trauma. On Facebook, one popular page called “Chinese Revolution” (with 155,000 fans as of November 2012) satirized the events in Syria as if they were happening in China. The page spawned several spinoff pages, including CHANA (mocking the Syrian Arab News Agency, or SANA) and the Chinese Electronic Army (satirizing the Syrian Electronic Army).

Memes have also occurred in the form of the Twitter hashtag. One such hashtag, #WhenAssad Falls, circulated in March 2012, and prompted both humorous and serious propositions for the end of the Assad government.

T

Take the Pledge

During congressional election campaigns, many interest groups will only endorse candidates who “take the pledge,” and promise that if elected, they will support the group’s policy agenda. Reciprocally, failure to take the pledge can result in the interest group supporting an opposing primary or general election candidate. In recent election cycles, interest group pledges have proliferated, covering issues such as taxes, abortion, social security, and government spending. Although many interest groups require candidate pledges, perhaps the most recognizable and controversial is Americans for Tax Reform, run by Grover Norquist. The Americans for Tax Reform pledge reads as follows:

I, _____, pledge to the tax payers of the _____ district of the state of _____ and to the American people that I will: ONE oppose any and all efforts to increase the marginal income tax rates for individuals and/or businesses; and TWO, oppose any net reduction or elimination of deductions and credits, unless matched dollar for dollar by further reducing taxes.

In the 112th Congress, all but six Republicans in the U.S. House of Representatives signed the pledge, along with two Democratic members;

this made a total of 238 signers in the House, which is the majority of the body. In the Senate, all but seven Republicans signed the pledge, along with one Democratic senator; this made a total of 41 pledge signers in the Senate, and a total of 279 pledge signers throughout the entire 112th Congress.

Another example of an interest group pledge comes from the Progressive Change Campaign Committee. In the 2012 election, the group created the Social Security Protectors Pledge. The pledge asked for legislators to oppose cuts to Social Security; the text is as follows:

Social Security belongs to the people who have worked hard all their lives and contributed to it. Social Security is a promise that must not be broken. We need to strengthen Social Security, not cut it. That is why I oppose any cuts to Social Security benefits, including increasing the retirement age. I also oppose any effort to privatize Social Security, in whole or in part.

In contrast to the pledge from Americans for Tax Reform, the Social Security Protectors Pledge had a much larger support and percentage of signers from the Democratic Caucus of Congress. A total of 110 members of the House of Representatives and 11 senators signed the Social Security

Protectors Pledge, all Democratic members, with the exception of one independent.

Enforcement and marketing for these pledges were elaborated, like any other pledge, over the 2012 election cycle by immense use of social media. Americans for Tax Reform used Facebook, Twitter, and YouTube to promote their message and encourage the American public to contact their congressmen and senators, and urge them to sign and pledge. Americans for Tax Reform as well as the Progressive Change Campaign Committee, released numerous YouTube videos as advertisements during the 2012 election, and teamed up with various groups on social media sites to promote their policy platform. Social media have become the largest sources for campaign advertising and promotion for interest groups that hope to spread awareness and gain support for their policy agendas.

There are both advantages and disadvantages for the interest group in such a system. The pledge system simplifies choices for voters. This is because the pledge system allows voters to see what policies they agree with and oppose, as well as see which candidates and legislators fit their policy agenda. By so doing, the voter will be able to recognize who they want representing them in office, with a reason behind it. Additionally, the system, at least symbolically holds the legislator who signed a given pledge accountable for upholding a particular policy. However, a pledge reduces the latitude that a legislator has in terms of the give and take of policy production. Compromise is the heart of the American legislative process, and the thrust of the pledge is to minimize the likelihood of meaningful movement on a given issue.

Moore, Stephen. *Who's the Fairest of Them All?: The Truth About Opportunity, Taxes, and Wealth in America*. New York: Encounter Books, 2012.

Taxes

Taxes are an exaction on income or wealth for public use. However, this has been extended by the courts to the much broader term of *public purposes*. Taxing and spending are closely related. The taxing authority for the central government of the United States (the federal government), is located in Article I. Section 8. Clause 1 of the U.S. Constitution, which says,

The Congress shall have power to lay and collect Taxes, Duties, Imposts and Excises, to pay the Debts and provide for the common defense and general Welfare of the United States; but all Duties, Imposts and Excises shall be uniform throughout the United States.

The taxing power is one of the "expressly delegated" or "enumerated powers" that are granted to the government of the United States. The use of taxes for the general welfare is the General Welfare Clause, while the requirement that all "Duties, Imposts and Excises shall be uniform" is the Uniformity Clause. The power to tax is limited. The General Welfare Clause has been contentious since the beginning. The loose construction of the clause sees it as a new spending power, while the strict construction of the clause sees it as restricting taxing power. However, in 1936, in *United States v. Butler*, 297 U.S. 1, the Supreme Court moved to accept the broad interpretation. However, there are still limitations. In Article I. Section 9. Clause 4, the power is restricted to deny taxing exports: "No tax or duty shall be laid on articles exported from any state."

The U.S. Constitution allows for a direct tax, a tax that cannot be transferred to someone else, upon individuals. Article I. Section 3. Clause 3,

says, “Representatives and direct taxes shall be apportioned among the several states which may be included within this union, according to their respective numbers . . .” However, Article I. Section 9. Clause 3, says, “No capitation, or other direct, tax shall be laid, unless in proportion to the census or enumeration herein before directed to be taken.” The per capita tax became the income tax with the adoption of the Sixteenth Amendment. Adopted in 1913 through the efforts of the Progressive movement, it allows the following:

The Congress shall have power to lay and collect taxes on incomes, from whatever source derived, without apportionment among the several states, and without regard to any census of enumeration.

In effect, it creates a legal fiction that instructs the Supreme Court to ignore the fact that it is a direct tax levied without regard to a census.

The various states have independent taxing authorities. Their respective constitutions usually prescribe limits on the taxing powers that they can exercise. For example, the Constitution of Georgia restricts property taxes to a maximum of 20 mills, or \$0.002 times the value of a piece of property. The various units of regional or local government in the states derive their taxing authority from their respective state governments. Taxes may be used to achieve some moral or social purpose of a government. For instance, medical workers pay a controlled substance license fee. However, when illegal drug dealers fail to pay the tax, their tax evasion is often easier to prove than other charges. The forms and types of taxes may be limited only by the imagination of the rulers or politicians seeking revenues. Taxes have been levied upon people as a direct tax, upon their stocks of physical money such as gold, upon intangible assets such as stocks and bonds, on activities, and on income.

Direct and Indirect Taxes

Taxes are considered direct if they cannot be passed to another individual or entity. Income taxes or corporation taxes are taxes on personal or corporate earnings. They are direct taxes, as are per capita taxes. Indirect taxes are those that can be passed along to others. For example, the

state and federal fuel taxes that Americans pay at the pump are passed along by the oil companies doing the drilling, refiners, wholesalers, pipelines, and tank trucks that deliver gasoline or diesel to a service station. The station then acts as a tax collector, collecting tax from the consumer pumping fuel into a vehicle.

People who support income redistribution usually support progressive taxes, such as income taxes that are taxed on the principle that the more one makes, the more one pays. Critics complain that progressive taxes are a punishment for success. Usually, the opponents of direct taxes support indirect taxes, which are levied at the same equal rate upon all who purchase a product or service. Their claim is that indirect taxes punish the poor. The claim is that statistically, the poor pay a higher percentage of their income than the more prosperous. Taxes have always been controversial in American history. The American Revolution developed out of opposition to taxes levied on behalf of King George III by Parliament. The Sugar Act, Currency Act, Stamp Act, and others sparked opposition to taxation without representation as the American colonists were forced to pay taxes that were levied without their consent. The Tea Tax invoked the Boston Tea Party and the events that led to armed conflict.

Taxes in the United States may be consumption taxes, used to reduce the consumption of products such as tobacco or alcohol. These are known as “sin taxes” in some regions. Excise taxes may be levied on the manufacture, transportation, purchase, or consumption of certain items. Certain kinds of licenses to engage in certain trades, professions, or to deal in certain commodities may also be subject to excise taxes. The Whiskey Rebellion of the 1790s was an unsuccessful uprising against an excise tax. Other taxes may be excise taxes, which are usually taxes on luxuries. However, a tax on vaccines may be part of a collection for paying for the treatment or loss of a child or adult who suffers or dies for a reaction to a vaccine. It may be for environmental cleaning after mining, or for used oil disposal. A tax on “Cadillac” health care plans is such a tax.

Unpopular taxes include estate taxes on inheritances. For most Americans, their estates are too small to require the payment of any inheritance taxes. However, many family farms or small

business are prudent to have an insurance policy to pay the death duties that might otherwise require the sale of a farm or the liquidation of a business. Besides personal taxes, there are business taxes for all manner of enterprises, including corporations. Taxes on imported products (tariffs) or entry fees are really taxes, even if they are not reported as such. The list of types of taxes is long and grows with the invention new taxes, such as a carbon tax.

Tax policies also allow for the exclusion from taxation of many sources of revenue. For example, nonprofit organizations such as churches (or other religious organizations), charities, and schools, foundations are not taxed. Their revenues are usually used to further socially important purposes that would either require government money to supply, or for a worthy purpose such as the fees to visit a museum would require that these social and educational institutions be close or curtailed. In addition, the tax code, which is a page for the tax rates and volumes to list the many tax exemptions, permits individuals and businesses to exclude or exempt income or taxes.

Lobbying

Because taxes are so numerous and important for the survival or success of individuals, businesses, nonprofit organizations, and governments, they are the subject of an enormous amount of lobbying. Washington, D.C., and the various state capitals are filled with individuals and permanent organizations that lobby on tax issues. It is unlikely that there is a tax that does not have organizations lobbying for or against the tax. As use of social media grows, they allow virtual communities to arise, and they can then move closer to legislators, lobbyists, or other policymakers. However, there are dangers for nonprofit organizations if they use social media to lobby because they could lose their tax-exempt status. Creating a lobbying organization is safer.

Americans have been subjected to acrimonious debates over taxes since the adoption of tax cuts by the Bush administration from the Economic Growth and Tax Relief Reconciliation Act of 2001. The sweeping legislation, also known as the “Bush tax cuts,” was bitterly denounced by Democrats and others as tax cuts for the rich, whereas it was strongly supported by Republicans and

others. The legislation was kept by the Obama administration, and would have expired January 1, 2011, but was extended two years by the 2010 Tax Act. It expired on January 1, 2013, following President Obama’s victory in the election of 2012. Obama’s proposals for more taxes to generate deficit reduction income and to avoid the looming fiscal cliff did not gain support.

The battle over the Bush tax cuts was comingled with other bitter tax debates between opponents in the very partisan culture wars. It developed in the United States in the 1970s, and continues today between those who want free public expression and practice of their religious values versus those promoting a monopoly of secular values. Among the institutions affected are public schools, which are increasingly at the center of political disputes between those who believe that their taxes are paying for an education that is hostile to their religious beliefs. The culture war, an increasingly bitter clash of values, has spread to other areas of life, including health care, with the adoption of the Patient Protection and Affordable Care Act of 2010 (PPACA). The act is often called “Obamacare” by its opponents, partly because of its tax increases. Other areas of life are also affected, some of which involve tax issues. Observers have noted that the culture war in the United States is not a matter of rational debate or accommodation, but a bitter struggle for domination in order to impose the values of one side on another.

At the heart of the culture wars are deep moral divisions between Americans. These divisions define not only what religiously is right and wrong, but also economically, ethically, politically, and therefore what is right in terms of taxes. Taxes are artificial social constructs that reflect the values of society. To institute a tax system or to make major changes in a tax system, changes to the tax culture usually have to be made. These changes include changes to the economic, social, and political culture of the day. Tax conflicts can be over what taxes to adopt, versus how tax revenues should be spent. They are often closely linked. Some taxes, such as those involving fossil fuels, may be of concern to business people, but are treated as a cultural issue by environmentalists. Even with what appears to be a nonmoral tax issue, it is necessary to persuade policymakers and their constituents that the policy is “fair.”

Some tax issues stem from the culture war. Some, such as the levying of sin taxes on alcohol and tobacco sales, have a long history. Others are relatively new, such as vouchers for school choice, and funding the National Endowment for the Arts, Public Broadcasting System (PBS), and abortions. There are blogs that deal with these; usually the blogs have social media resources such as Twitter, YouTube, Facebook that allow opinions generated by reading the blog to be spread.

Government Spending

Tax conflicts over what taxes to adopt, versus how tax revenues should be spent, are often closely linked. Some taxes, such as those involving fossil fuels, may be of concern to businesspeople, but are treated as a cultural conflict issue by environmentalist seeking a carbon tax. Even with what appears to be a nonmoral tax issue, such as a capital gains tax, it is necessary to persuade policymakers and their constituents that the policy is “fair.” In 2011, the National Society of Accountants launched a social network in order to discuss IRS tax forums and other tax issues for accountants and others engaged in tax form preparation. Other Web sites have been created for tax professionals to have a forum for discussing tax issues, including the ethics of taxation and tax avoidance. For example, a proposal to eliminate a tax subsidy for farmers would very likely require a change in their beliefs about what is a fair farm tax policy.

Social media are an emergent technology that has been adopted by different sides in the tax culture war. Some of those engaged in the conflicts over taxes are opportunists who seek changes in tax policy for their interests, and are not especially concerned about the cultural issues affected by taxes. Many types of social media were used in the election of 2012. Some of these focused on candidate tax policy positions. Others were blogs that focused on tax issues, such as tax havens or revenue-neutral claims.

The Tea Party Movement in 2012 was a diverse movement that made even more use of social media as it sought to reduce government spending and limit taxation. In contrast, liberal or progressive organizations such as MoveOn.org used social media to organize and inform their communities. Those who prepare taxes are also using

social media to communicate. Links in computerized tax preparation software can allow links to social media, with Facebook and LinkedIn the most popular. Information about tax planning and tax law is shared via blogs, Twitter, and other social media.

One of the new uses of social media is that made by tax collectors. People whose location was unknown or who have not paid taxes have been found via social media. State collection agents in particular have been able to locate and collect unpaid taxes. Or, they have learned of events at which the tax payer will collect a big fee, so an agent is sent to collect the appropriate taxes. Searches for tax cheats, tax delinquents, and scofflaws can include using social sites and chat rooms; however, agents are not allowed to “friend” someone. The growing use of social media is connecting people who can then debate taxing and spending issues. Government agents are as involved as citizens in conversations that historically took place around the kitchen table, rather than over the Internet. Social media user studies have found that they are more than twice as likely to be politically active than nonusers of social media. They raised much more money for candidates than nonusers.

Observers believe that social media use has changed American elections forever. During the presidential and vice presidential debates in 2012, tweets swarmed into the ether following comments that could be interpreted as rhetorical faux pas. Social media was not “social” because it was used to disseminate positions (or poison), rather than for the debate of issues. Pushing messages by candidates and their supporters on social media bypassed the restraints that filter journalists. The elite pundits and journalists used social media to engage each other. The anonymity of Twitter and some other social media allowed vicious comments or images to be spread between elites and their minions. The increased discussion did not, however, increase political knowledge as partisans sought to slime, “snark,” or savage each other. The most telling impact was the ability of elites to frame issues and images that were then disseminated by their followers. The social media framing of stories was in many cases sufficiently powerful to frame the traditional reporting of stories on candidates, and even taxes.

Given the eventual outcome of the Obama administration's tax agenda, many argue that the White House's use of social media as a means of galvanizing popular support for its tax plan dramatically "fizzled out." This includes the White House's attempt to employ Twitter, in particular, as a means of dominating the social media discourse around this specific instance of American "culture war" waged on the battlefield of national tax policy.

discourse closer to the right than it has been in quite some time. The 2010 midterm elections showed the potential power of social media in American politics. Concerned with a looming financial meltdown, government stimuli, bailouts, and the 2008 election of Democrat Barack Obama as president of the United States, a movement of fiscally and socially conservative Americans calling themselves the Tea Party (for Taxed Enough Already) surprised the country by defeating a number of entrenched politicians. Beyond citizen attitudes toward government and alleged tax-and-spend liberals, many believe that social media was the vehicle that allowed the Tea Party movement to reach its full potential. As such, the Tea Party has been highlighted as an example of how social media can truly impact social change.

History

Only two years after Obama won the presidency and seemed situated to return Democrats to the forefront of national politics, Republicans roared back. But it was not only the typical Christian conservative voter leading the way. Instead, it was a collection of angry, middle-aged, white fiscal conservatives, many but not all of whom share the ideological agenda of the Christian Right, who took aim at national officials. Before turning on Democrats, they chose to turn on incumbent Republicans who they believed were too moderate in their beliefs. Even while President George W. Bush had been in the White House, many fiscal conservatives were unhappy with his administration's decision to give bailouts for banks and for propping up automakers. With Obama in office, these fiscally conservative Republicans grew more vocal about spending. Online networks permitted these individuals to come together across the country, also attracting supporters interested in advancing deeply conservative perspectives on a host of social issues, and their voices began to collectively resonate in a major way.

The initial foray of the Tea Party into social media was likely the Smart Girls Politics blog started by stay-at-home mom Stacy Mott. Mott had become fed up with how the federal government (in all branches) was handling the national economy, especially governmental bailouts. Her blog and social network were aimed at

Tea Party Movement

The biggest story of the 2010 U.S. midterm election was the increasing influence of the Tea Party movement. Since their first rallies in early 2009, these vocal, visible conservatives have succeeded in shifting the center of American political

conservative women who shared her economic concerns. The content eventually caught the eye of Michelle Malkin, and began to gain readers.

On February 19, 2009, Rick Santelli, a CNBC commentator, was broadcasting live from the Chicago Board of Trade. He had doubts about the government's response to the economic meltdown. While on air, Santelli became increasingly angry, and indicated that he was planning a "Chicago Tea Party." After Santelli's rant, the Smart Girls Politics blog went viral, from approximately 400 viewers to thousands overnight. Santelli had struck a chord with the American public. At the same time, hundreds of new blogs began appearing, all focusing on the federal government's misappropriation of money and handling of the economy.

A Tea Party member in early American costume waves a flag of protest outside of the U.S. Congress building on Capitol Hill in Washington, D.C., during a protest against President Barack Obama's health care reforms on March 20, 2010.

A simple idea had quickly become a grassroots cry for something different.

A few weeks earlier, on January 24, a few dozen citizens of Binghamton, New York, poured soda into the Susquehanna River. The familiar symbolism of the Native American headdress was utilized to protest a slate of taxes endorsed by Governor David Paterson, particularly a tax on soft drinks. Trevor Leach, a spokesman at the protest, noted: "We really want to see a sense of fiscal responsibility from the government and have them get their hands out of our pockets." Recognized as the first Tea Party protest, the Binghamton demonstration exhibited an underlying current of dissatisfaction with the scope of government and resultant policies in a regional setting. However, these early scattered, disparate protests would soon coalesce into something closer to a national movement.

Social Media

Outside of the initial blogs, social networking sites became a key element of the Tea Party. Through these means, members were able to share videos and pictures of rallies, demonstrating to the world both their seriousness and following. Facebook pages were the first to emerge. Because the Tea Party has always prided itself on comprising a connection of local activities, rather than a top-down organization, these pages proved pivotal for coordinating activities. Shortly after the movement's emergence, Facebook was the central calendar for all group activities. Before the end of the first year, well over 3,000 Facebook pages were attached to the Tea Party.

Twitter was equally important for the Tea Party in its early days. A group of top conservatives using the hashtag #tcot began with only 25 members, but quickly grew to well over 1,000. Once membership expanded, the hashtag was used to organize town hall meetings, conference calls, and rallies, and to bring together citizens across the country in one place for the world to see. In order to make sure that information stayed in one place, organizers switched to utilizing wikis. Through this platform, they were more able to provide advice related to protest strategies and organization techniques.

In short order, the ragtag collection of complaints about government spending became a

cause. When Scott Brown successfully won Ted Kennedy's Senate seat in Massachusetts, it was clear that the Tea Party mattered. But not everything was perfect. Articles showed that the initial loose organizations created through social networks had begun to unravel as a result of fighting among groups. National organizations appeared and attempted to take over the ideology of the Tea Party movement. Closer scrutiny of the Tea Party's financial resources kicked off a debate over its self-description as a grassroots movement of "ordinary citizens." Increasingly inflammatory discourse on both sides of the issue heated up even further when the *New York Times* claimed that the movement's three biggest funders were media magnate Rupert Murdoch and Wall Street financiers David and Charles Koch, an allegation that was, subsequently, denied by the Kochs and others. Compounding these funding controversies were other issues.

As the initial euphoria around the movement's early momentum began to disappear, social networks were unable to keep the movement going. After all, the strengths of social media lean toward bringing people together and sharing messages, not rectifying differences or working through political battles. Social media was not as successful as traditional media in bringing national attention to the organization. Fox News, the *New York Times*, and the *Wall Street Journal* took the time and energy to carefully study the movement and its followers.

A study by the University of Michigan zeroed in on the tweets of self-identified Tea Party members. Despite its grassroots nature, the Tea Party appeared to be running an organized campaign. Not only did members tweet more often, averaging 901 tweets during the study period, they exhibited behaviors suggesting a stronger community than their counterparts. Tea Party members retweeted one another more often, rebroadcasting a colleague's message an average of 82.6 times, compared with 52.3 retweets for Republicans and 40 for Democrats. They used hashtags (keywords preceded by the # symbol used to categorize tweets) an average of 753 times, compared with Republicans' 404 times and Democrats' 196 times. The researchers suggest this may be because the Tea Party members joined forces on Twitter to attack key Democrats. Among the

party's most popular terms were "Nancy Pelosi," "Barney Frank," and "Clinton."

Characteristics

Prior to April 2010, many Americans, particularly liberals, operated on the belief that the Tea Party was the "flamboyant fringe" that David Brooks described. They were assumed to be uneducated, extreme right-wing patriots who opposed Obama on the grounds that he would bring socialism to America. The American media focused on the misspelled signs and apparent misunderstanding of government programs and economic decision making to paint the entire movement as more sizzle than steak in regard to the movement's potential.

In April, a combined CBS News/*New York Times* poll was released that directly refuted much of the general public's perception and helped show America who the average Tea Party supporter was. Many believed that the Tea Party solely emerged from dissatisfaction with Obama and Democrats, but the CBS News/*New York Times* poll shows that 92 percent of Tea Party backers were at least somewhat dissatisfied with both traditional American parties.

However, Tea Party supporters, as suggested previously, are less likely to believe America needs a third party to compete with Democrats and Republicans than the average survey respondent, believing instead that the Republican Party has strayed too far away from its conservative roots and that government in general needs an infusion of new blood to counteract the complacency and cronyism that they feel has infected Washington politics. The one thing the media seemed to peg correctly was how the Tea Party focused far more heavily on economic than social issues, with 78 percent stating that economic issues were the most important considerations in the lead-up to the elections.

Tea Party supporters are educated and wealthy. They were called to action on the wings of the economic recession of 2007 and the election of a president who spoke of more government spending. They want to remain a network of independent organizations that primarily focus on pushing their issues, not individual candidates. However, they also realize that in many elections, the only way to do so will be by promoting candidates.

The Tea Party movement has succeeded by connecting local groups to the national conversation. Followers relied on new media sites like Facebook and Twitter to follow the movement especially in its infancy.

Because the localized groups were at best loosely connected, they were limited to social media to learn what was happening with similar groups across the country. While large umbrella groups, such as FreedomWorks, were occasionally accused of attempting to dominate the smaller groups, they also provided the needed social media training for groups to be successful in reaching followers. Grassroots groups were able to take off once localized chapters were given the proper tools to share their beliefs, methods, and results.

Impact

Contrary to the predictions of many, the Tea Party had a real impact on the 2010 elections. Whether it was by helping to unseat Democratic senators or forcing moderate Republican hopefuls to become more conservative in their beliefs, the Tea Party showed the potential to be a lasting political force within the nation's politics. Considering that prior to the 2010 elections, the Tea Party had been referred to as a right-wing response to Obama, racist, unsustainable, or not fully committed to its beliefs, it is even more remarkable how the network of local organizations was able to prove naysayers wrong across the country about their possible electoral impact.

Originally deemed an un-American astroturf campaign by Nancy Pelosi, the Tea Party instead helped to usher in the era of Speaker John Boehner and the Republican Party in Washington, D.C. After the rank-and-file Tea Party members were largely dismissed as crazy ideologues, Tea Party candidates were dismissed in much the same manner by the traditional party establishment.

When the more conservative, Tea Party-supported candidates proved victorious in primaries across the country, moderate Republicans realized that they had been stuck in the middle to lose. Without social media, however, the organization may have never grown into the powerful political player it is today. While Barack Obama waged a successful social media campaign in 2008, Tea Party activities showed Republicans

how they can do the same between his inauguration and the midterm elections.

Technological Determinism

Determinism conceives of the world as fixed and objectified, and therefore predictable; free will is nearly, if not completely impossible, and life options are outside of human control. For instance, biological determinism is a kind of

determinism that suggests that genetic traits dictate how one should live and what one can do. Some people have argued that sex determines the careers a person is (not) allowed to seek (e.g., arguments such as that women are genetically too weak for the military, or that men are genetically incapable of being good caregivers), and that particular traits are natural, unchangeable, and thus uncontrollable for some kinds of people (e.g., aggression and violence in men or emotion and irrationality in women).

Technological determinism is another kind of determinism. Technological determinists work to find direct and causal relationships among a medium/technology, human behavior, and cultural life, and they often focus on the role that a dominant medium plays in a specific era (e.g., writing, printing, television, computing, and smartphones), particularly how the medium influences on cultural change how one relates and lives.

There are two kinds of determinism: hard and soft. Hard determinists make reductionist, causal, and often uncompromising claims about the role and impact of technology on human behavior and cultural life; often, a particular, dominant medium or technology becomes the “sole” cause of social change. Hard determinists might say that books cause individualistic thinking, television makes children violent, smartphones make people less social, and the grammar of texting and text-speak makes people less intelligent. Hard determinists assume that few differences exist in the use of or exposure to dominant technologies, and that cultural change only happens because of these technologies.

Soft determinists offer more tentative and nuanced reads of media and technology; they view media and technology as one factor in, not the sole contributor to, human behavior and social change. For instance, a soft determinist might say that books may cultivate individualistic tendencies, television can contribute to violent actions, smartphones complicate classroom settings and interpersonal relationships, and texting and text-speak changes language, grammar, and spelling in innumerable, unpredictable ways. For a soft determinist, mediation becomes one of the many focuses on how a particular technology influences cultural life.

Marshall McLuhan and Walter Ong

The two scholars most closely associated with technological determinism are Marshall McLuhan and Walter Ong (a student of McLuhan). McLuhan argued that technologies act as extensions of the human senses—they enhance one’s embodied abilities (e.g., clothes protect us from the weather; glasses allow one to see better/more; cars, trains, and planes collapse space and time) as well as how one relates to/with others (e.g., games promote sociability; clocks promote productivity and punctuality; money quickens exchange; and cars, trains, and planes allow one to be/feel closer to friends and family). McLuhan is also known best for his “the medium is the message” aphorism, which calls attention to the form of a message and indicates deterministic thinking.

For instance, consider a news broadcast about crime. Instead of only analyzing what a reporter said about crime in the broadcast, McLuhan encouraged researchers to investigate how the form—the medium—in which the broadcast appeared (e.g., television, radio, or online) influenced persons’ understandings of the content. A hard determinist read of “the medium is the message” would suggest that one look at nothing else but the medium’s influence on the message—the medium “is” the message and “the” message that matters most. A soft determinist read of “the medium is the message” would suggest that the form and content—the medium “and” the message—are mutually constitutive; a news report about crime may be molded to fit a 30-second time slot on the evening (televised) news, but it is also important to note how the crime was described and what images may have been used. Additionally, the interested viewer may be able to access other coverage of the crime online through news sites, blogs, and video sharing sites like YouTube, with each form modifying the message.

While McLuhan considered the various workings of specific technologies, Ong examined broader cultural changes tied to the invention and use of particular dominant technologies. Specifically, he outlined characteristics of oral cultures (groups that valued storytelling, repetition, and limited vocabularies), literate cultures (groups that valued writing, linear thinking, individualism,

and expanding vocabularies), and electronic cultures (groups that valued storytelling, repetition, writing, linear thinking, and individualism). Ong argued that new technologies do not eliminate the characteristics of earlier technologies; instead, new technologies continue or reframe the use of earlier technologies.

For example, most television and film scripts rely on repetition and redundancy, techniques typically associated with oral cultures. For example, the common mystery movie often requires the repetition of clues so that and can understand how Sherlock Holmes solved the puzzle. However, the plot does not follow a simple chronology as typically expected in an oral text, for example, the producers of *Sherlock Holmes* use literary conventions to heighten suspense—conventions similar to those found in (written) mystery novels. A person may also access the same story through various media. For example, vampires appear in fiction, films, video games, and blogs, as well as in Victorian literature and silent films. Each medium contributes to how a person might understand and interpret vampires.

Technological determinists work to explain how various media aid in the construction of culture, communication, and everyday experience. Currently, most scholars take a soft, inclusive, and nuanced approach to technological determinism, for example, understanding that the existence of television or watching violence on television does not turn people violent; the viewing of violence may help cultivate an orientation toward violent behaviors, but a direct, causal relationship between television violence and violent behavior is just too simple.

While some scholars have historically considered technological determinism in causal and predictable ways, contemporary understandings of technological determinism are more fluid; scholars are much more interested now in how technologies “may” change human behaviors, rather than discerning firm and rigid perspectives on people’s relationships to technological invention and innovation.

Technological Relativism

Technological relativism serves as an umbrella term for a wide range of ideas, theories, and approaches that are bound together by the shared theoretical belief that technology in itself does not drive social change, but rather it is ultimately shaped by social and cultural forces. Central to this belief is a general skepticism against any predetermined notion of technology’s role in the progress of society or the autonomous power of technology. Thus, it stands in sharp opposition to technological determinism. In contrast to, for instance, Marshall McLuhan’s deterministic idea that posits that certain intrinsic attributes of a dominant technology exert great influence on the main communication mode of the time as well as the social structure, the relativist would assert that the invention, evolution, and deployment of technology must be understood with regard to its broader context, one that is marked by the fabric of social, cultural, economic, political, ideological, and regulatory forces.

This antideterministic stance derives much of its theoretical appeal from the broader intellectual

movements such as philosophical relativism, pluralism, postmodernism, and British cultural studies, that call into question such notions as universal rationality, absolute truth, and objectivity. Technological relativism focuses on both the complexity and contingency of technology. It refuses to see the technology–society equilibrium in a simple linear, cause-and-effect fashion. In favor of considering the social context of technology, which may be both enabling and restrictive, technological relativism strives to discredit any attempt at discovering or establishing universal standards or principles of technology that transcend space and time. This theoretical effort takes various forms, from strong cultural relativism to social construction of technology and critical cultural studies of technology.

Despite technological relativism's many different forms, a number of important common assumptions and perspectives can be distilled: First, technological relativism sees technology as a human invention, and it accordingly stresses the importance of human agency. Under this view, technology in itself does not have an intrinsic final end, but rather it is the human agent that develops and uses technology to meet certain social needs. For the relativist, the notion of determinism is troubling when it seeks to find or predict the universal path of technological innovation and diffusion. Second, it asserts that a technological artifact, if placed outside of its social context, has little to no significance, so it pays special attention to the social shaping or construction of technology. While humans are free to make technological choices, such choices must be made within the constraints of the time. The social context does not function as a mere backdrop for the smooth, seamless acceptance or refusal of technology. Instead, it serves as a site in which various tensions, conflicts, collaborations, and negotiations interact to shape the contour of technology. Technology is now better understood as an intervention into the relationship between human agency and social structure. Third, it also highlights the role that culture plays in the shaping of technology. Society influences technology not only through formal institutions and regulatory mechanisms, but more importantly via cultural traditions, routines, myths, and desires. Technology cannot avoid facing these multilayered, deep-seated

cultural influences, nor is it possible to examine technology out of this cultural context. Last, it takes a careful look at the power relations embedded in the technology-society relationship. In other words, the adoption and wide use of a new technological invention can be either promoted or suppressed by the existing power structure and its hegemonic relations. Consequently, the extent to which a new technology is adopted by society is determined as a result of an interaction between the force to maintain the status quo, and another force to undermine it.

Technological relativism possesses certain advantages over deterministic ideas. Most importantly, it provides a theoretical basis for a contingent, context-specific explanation as to the roles that larger society or culture play in shaping the contour of technology. Therefore, it helps challenge overly reductionist, indiscriminate ideas that prefer to isolate specific, empirically verifiable properties of technologies from their social contexts. It also better reflects some of the most salient values of contemporary democracy, diversity and pluralism. On the other hand, it draws some weaknesses. While technological relativism places a well-reasoned emphasis on the complexity of interaction between technology, society, and culture, it has been criticized for its inability to examine certain intrinsic values of a new technology that may be qualitatively different from the preceding ones. That everything is relative can be criticized by the presence of certain universally adopted technological innovations that show little to no cultural imprints. A second disadvantage is that relativism may result in theoretical chaos or anarchy. Being relative means accepting diverse, pluralistic theories and methods, and in turn this can result in incoherence in theory. Also, it can be overly descriptive, lacking explanatory or predictive theoretical power.

Debate

In light of the increasing role that social media play in contemporary politics and democracy, the heated debate between technological determinism and technological relativism has recently been enlivened. While technological determinism pays attention to the internal distinctive attributes of the technology in fostering democracy, technological relativism pays greater attention to the

roles that culture and social context play in conditioning the actual use, deployment, and effects of the new communication technology. The relativist would argue that the degree to which social media are used for democratic ends is essentially dependent on different sociopolitical contexts. As can be seen in the case of the Arab Spring and elsewhere, social media can be used not only by protesters, but also by state censors. Therefore, technological relativism may well inform cross-cultural or international comparative research on the use of social media for contemporary politics and democracy.

Technology Diffusion Paradigm

A predominant theory used to understand the spread of social media is diffusion of innovations. While research has been conducted on technology diffusion since the 1940s, the concept of diffusion of innovations has shown remarkable resilience and portability across various areas of social science. Diffusion of innovations is particularly useful in understanding the spread of

media in general, and social media in particular. Not only does the concept explain the spread of the Internet, but also the process by which social media have become embedded so quickly in people's lives.

The term *diffusion of innovations* was coined by Everett Rogers during his research on the spread of agricultural innovations among farmers. The theory seeks to explain the spread of an idea or technology through a population. It suggests that the process of introduction and adoption of a new idea or technology is similar for different types of innovation and for all populations.

Early innovation researchers postulated that the diffusion of ideas and technologies would behave much like the spread of a disease epidemic through a population. This meant that there would be a point of introduction to the new population, then initially the idea would be accepted by only a few people, but as more people adopted the idea, the rate of dispersion would accelerate until it reached a point of saturation in the population, when the rate would slow down. The spread of an innovation, like the spread of an epidemic, would take the form of an S-shaped curve.

Rogers states that the dispersion of any technology goes through four stages: invention, diffusion, time, and consequences. According to this supposition, a technology first has to be conceived, tested, and implemented during the invention stage. After invention, the idea or technology is then offered for consumption to the general public and is gradually accepted into a population. Over time, the innovation reaches a point of saturation or tipping point. Once the innovation has reached enough people and has spent enough time in a population, the impact or consequences of the adoption of this technology become evident.

Obviously, not every technology or idea introduced into a society is equally accepted. This is because the technology has to be properly communicated to the target audience. According to the diffusion of innovations, while the technology can be simultaneously communicated to a large population, each individual has to go through a personal five-step process of decision making. The five steps are as follows:

1. Knowledge, in which an individual becomes aware of a technology and its features
2. Persuasion, in which a person evaluates the technology's benefits and costs
3. Decision, in which a person accepts or rejects the technology
4. Implementation, in which the individual begins consistently using the technology
5. Confirmation, which consists of a formal or informal review of the technology and its usefulness.

Additional factors in the diffusion process are the personal characteristics of individuals in a society. The population can be divided into five adopter categories: innovators, early adopters, early majority, late majority, and laggards. Innovators are usually excited about trying out new ideas, and tend to be technologically adept. Early adopters tend to be the opinion leaders in their society, and judiciously use the data generated by the innovators in their decision-making process. Early majority adopters constitute the tipping point of the diffusion process. These individuals, while not risk takers, are socially well connected and accelerate the process of diffusion through their personal connections. Late majority adopters are a more cautious bunch, and will often only use the technology once it has become well accepted in society. Laggards are late to join in, either because they are holding onto traditions challenged by the new technology, or because they are economically or socially disadvantaged in accessing the technology.

Ordinarily, the diffusion of an innovation through these five population categories follows a bell curve, where a few innovators try out the innovation in the beginning (2.5 percent). If all goes well, early adopters come onboard, making up the next 13.5 percent of the population. Both the early majority and the late majority make up 34 percent of the user populations. After 84 percent of the population has accepted an innovation, the laggards come onboard, constituting the final 16 percent of the adopting population. Of course, there are some populations and individuals who remain unable or unwilling to use a certain technology because of economic barriers (technology can be expensive) or personal reasons

(not all forms of technology are useful, let alone necessary, to different population segments). Additionally, many technology adopters “cherry-pick,” embracing specific types of technology that improve certain aspects of their particular lives while declining to use those that do not. One outcome of “opt-out” behavior in the user population would be the digital divide, which continues to persist, despite astounding technological advances.

This process of diffusion of innovations can be applied to both media channels and content. The distinctive quality of social media is the rapid pace of the diffusion process. The length of the process of diffusion of innovations for mass media has become increasingly compressed with each successive technology. Print, especially in the form of mass-produced publications, took a few hundred years to reach saturation. For radio, the diffusion process took about a century. Television reached saturation in a little over 50 years. However, the group of technologies collectively known as digital media have typically had a diffusion time range of two to 10 years, and this timeline is under further compression pressure.

Social Media

Regarding the diffusion paradigm, the distinctive characteristic of social media is that, as a whole, it is made up of different Web sites and apps that are at various levels of diffusion. This means that it is difficult to say with certainty what level the diffusion of social media as a whole has reached. Within the social media context, innovators are mostly young people, the technologically savvy, and social outliers, and many have already started using newer social media such as Instagram and StumbleUpon. Social media early adopters have turned out to be nonprofits, social movements, and politicians, all of who have been quick to grasp the potential of these technologies. The early majority are still at the stage of integrating apps such as Twitter into their daily lives. The people belonging to the early majority are typically older adults, and most are still at the stage of becoming comfortable with Facebook. People belonging to the late majority have concerns about issues such as privacy, as well as those affected by the digital divide. These are people still gaining comfort with technologies such as texting and reading

blogs. Finally, laggards tend to be older adults and people affected by the digital divide; they are still coming onboard with core social media apps such as smartphone messaging and e-mailing.

Television and Social Media

The television ecosystem is in mutation, regarding both production processes and reception tactics. Although television's entertainment content is the primary concern of social media, important implications for the political use of the television/social media nexus are embedded within these less overtly political issues. Because viewers for any given time slot are increasingly fewer and spread across a wide range of channels, interactivity and audience participation are becoming increasingly valued in TV programming. In a society where screens are colonizing a variety of environments (e.g., work, entertainment, and administration), television has to adapt to new ways of consuming programs, whether news, reality shows, documentaries, or TV series on multiple devices such

as TV sets, smartphones, tablets, and desktop or laptop computers. Social media, similarly accessible on a variety of platforms, provide a unique setting for networks and viewers alike to communicate with one another. These gathering places offered by social media further facilitate, and even foster, a number of fan activities for active consumers.

Audiences are fragmented and have acquired both the technological skills and the equipment to watch programs wherever and whenever they wish. Social media such as Facebook or Twitter offer audience members ways to show their appreciation for a program, discuss a program, or have access to additional content offered by networks. Moreover, the most active and involved of these viewers, fans, have various activities of creation and content production, ranging from writing could be/would be extensions of stories (fanfictions), video montages (fanvids), or creating costumes (cosplays), and are gathered in communities that spread media content within their communities and in the public sphere. These fans, in their quest for more knowledge and possession with regard to the object of their affection, are also the first to acquire DVDs and other products. Consequently, while the mainstream audience (and the various demographics composing it) remains the primary target of advertisers (and thus, television networks), fans have become the targeted audience of transmedia marketers (who disperse elements of the story across various platforms to create a unified entertainment experience), as well as the television studios that own the rights to the DVDs and the various consumer products.

Social Media Use by TV Programs

In order to reinforce interactivity and spread social links and connections, TV programs now include social networks in their narration or in their communication and promotion. Facebook is mainly used by channel representatives as a support for creating official fan pages, where TV viewers can find information on the programs they enjoy, interact with other fans, and tell others that they enjoy the show through the "like" button. Additionally, with regard to the statistics departments of TV networks, fanpages on Facebook represent a barometer of their shows' appeal because it allows them to instantly see

A viewer controls XBMC open source media player software on a PC connected to a television in 2012. The software allows users to watch and collect movies, television shows, and multimedia content from the Internet. New ways of consuming programs on multiple devices that include TV sets, smartphones, tablets, and desk or laptop computers have challenged traditional television platforms.

how many viewers like the programs, as well as to interact with these fans via Facebook posts. Fan discussions are not always positive and constructive, however, and social media can occasionally serve as an outlet where the audience may express their reaction, sometimes violently, toward something that has happened in relation to the program. A recent example would include the British series *Torchwood*, when fans violently criticized its recent Americanization by U.S. premium cable channel Starz, and attacked the writers for what they considered bad storytelling.

Different platforms offer different strategies. On Twitter, for instance, channels encourage their audiences to interact live during programs through the use of specific hashtags, which are words referring directly to the show (most commonly, the program's title or the name of a character or a situation that has recently occurred).

This strategy is an instant barometer for networks that can evaluate the number of viewers who are both watching and live tweeting, along with instant feedback on what the latter think of the program. TV viewers gather in virtual communities in order to (re)create a pseudo-common viewing experience via the use of a hashtag.

As a result, fans usually create personal hashtags, following a principle of fan communities, using their language and their decoding of the programming, thereby reinforcing a sense of belonging. Only those who are part of the community will join the conversation. When fans use their hashtags, rather than those proposed by the production team and appearing on the screen throughout the program, tweet tracking is much more difficult for channels and studios attempting to measure the fan following of their products.

Additionally, TV news channels are present on social networks, particularly on Twitter, where they share their latest news, sometimes retweeted thousands of times within minutes. In addition to these two main platforms, television networks also use other social networks such as YouTube as a means to disseminate trailers, teasers, and other sneak peeks of their current, past, and upcoming productions, rendering them instantly accessible and free to millions of fans and potential viewers across the world.

Fan Use of Social Media

In parallel to official accounts created by the networks, studios, and their official representatives, fans make use of social media by creating fan pages. They use Facebook, Twitter, and YouTube, where they upload numerous fanvids, use abstracts or programs, or make videologs (or vlogs) commenting on the latest episodes. Fans are also present on Foursquare and Pinterest, as well as on platforms specifically made for fan gatherings, expression, and activities such as Fanpop, where fans can gather; share pictures, videos, and links; ask and reply to questions; and create and participate to polls and quizzes. Moreover, social network/app GetGlue allows fans to share their viewing experience and keep track of their TV series schedule. They can win badges when they log on to watch a series and share their badges with communities through social networks such as Facebook and Twitter. With this application, they can show their tastes in TV shows and can once again gather in a community of viewers who share the same interest as a way to enhance their viewing experience.

Social networks also allow viewers to advocate some of their opinions and to conceive and implement virtual campaigns. The goal of such campaigns can vary from show to show, but are primarily related to saving a recently canceled program. Most of the time, these online pages will appeal to a physical campaign, which would see fans send letters or objects to networks, channels, or studios headquarters in the hope of convincing executives of the ongoing interest of the audience (and the continuing financial profitability of the program). Recent campaigns include the Save *Jericho* campaign, when fans sent more than 20 tons of peanuts to CBS headquarters in 2007, the Save

Veronica Mars campaign, which saw fans send over 10,000 Mars bars to the CW in 2008, or the Save *Chuck* campaign, which included sending letters, donating money on NBC's behalf, and purchasing Subway sandwiches (a brand heavily featured in the show) in large numbers during the finale.

History has shown that such campaigns can work. While the *Veronica Mars* campaign did not work, *Jericho* was given a second season, and *Chuck* was renewed for three consecutive seasons thanks to a financial partnership between NBC and Subway. Such successes have since fostered further hope and motivation to millions of fans across the globe. Convincing a network to renew a program for another season, or a different network to buy the rights of the show, are not the only aims of these movements. Other types of campaigns, for instance, include petitioning for a DVD release of an earlier show, or the theatrical adaptation or sequel of a program. Examples of these practices could include the Facebook page where thousands of *Twin Peaks* fans petitioned for the DVD release of deleted scenes from the prequel movie, *Fire Walk With Me*, or the 2013 Kickstarter campaign, petitioning for a *Veronica Mars* movie.

This paved the way, however, for an entirely different type of online fan campaign: Rather than seeing fans appealing to business practitioners for their help, this endeavor was just the opposite. This campaign was launched by the show's main actress, who appealed to fans for "fan financing," asking faithful viewers of the long gone program to donate even a small sum of money in order to reach the \$2 million goal, for the (most likely, partial) financing of a *Veronica Mars* movie, and promising different rewards depending of the size of the donation. In the end, over 90,000 fans donated money for the cause, which amassed nearly \$6 million in funds. Not all uses of social networks can be seen as franchise friendly, including those—most notably through discussion threads—that are employed to share links to illegal downloads, peer-to-peer or otherwise, as well as to Web sites freely streaming recently aired episodes.

Television Personalities and Social Media in Politics

News anchors and political pundits become media personalities, recognizable to individuals who routinely watch news programming. These media personalities provide citizens with information about politics, and must draw in consumers in order to keep their outlets profitable in a competitive media environment. Increasingly, media personalities have begun to use social media to fulfill both these roles. However, while the rise of social media has changed the relationship between media personalities and consumers, it may also have more detrimental political effects. Most citizens are not politicians. They do not sit in congressional or parliamentary hearings, nor do they attend local city council meetings.

These citizens receive most, if not all of their political information through the news media and the media personalities who cover politics. News media content provides citizens with the basic information that serves as a framework for their knowledge of political events. Yet, media personalities must do more than merely inform the public. When news media are privately owned,

news producers need to make profits to survive. As a result, media personalities must draw in consumers. These consumers may pay a fee for their news, as do newspaper subscribers. Consumers may also obtain the news product without paying a fee, as do network or many Internet news consumers. These nonpaying consumers provide profits to news producers by bringing in paid advertisers eager to sell their products to an outlet's audiences.

Connecting With Fans

Many media personalities have embraced social media as a mechanism that allows them to communicate information to viewers and draw them in. Today, media personalities covering politics often use Facebook (a social networking Web site), Twitter (a cell phone-driven social networking site), and/or YouTube (a video-sharing Web site) to reach out to consumers. These social media sites have the potential to reach a large number of consumers. For example, Facebook, Twitter, and YouTube are among the top 10 most visited Web sites, and together attract about 10 percent of all Internet users worldwide on any given day. The most recent estimates indicate that approximately one billion subscribers use Facebook to connect with their online "friends" worldwide. In the United States, at the end of 2011, Facebook had 133 million active users, who interacted with Facebook content at least once a month. Facebook users also spent a good deal of their Internet time on Facebook—an average of 423 minutes in December 2011. Twitter, while younger than Facebook, already boasts over 500 million subscribers. In the United States, research suggests that 66 percent of all adults who use the Internet participate in social networking sites.

The increasing use of social media has changed the landscape of today's mainstream news media, creating a more active consumer, and altering the relationship between media personalities and media consumers. Print news, radio, and television represent old media. These sources allowed consumers access to political information. However, they gave their consumers little control of news content, other than through market pressures. For example, individuals unsatisfied with the political coverage in a newspaper could choose to use another news source, taking away

subscription dollars from the unsatisfactory newspaper, and decreasing the size of the audience that publication had to offer to its advertisers. Old media sources also maintained a strict division between media personalities and consumers. Those readings a newspaper or viewing a program acted as passive observers, taking in the information presented by their sources. Beyond writing letters to the editor, consumers had few ways to interact with the media personalities they relied on for information.

Social media changes the nature of the relationship between media personalities and consumers. Media personalities use many different types of social media to reach out to consumers. Many mainstream journalists write Web logs (blogs). Others use Facebook, Twitter, and YouTube to share content and connect with consumers. These social media outlets create new places for consumers to obtain political information, allow much more consumer control of the media they receive, and provide consumers with a more interactive media experience.

Blogs allow media personalities to share their opinions on political events online. Those following a media personality's blog have the opportunity to comment on the blog's content or respond to the comments of others. Some bloggers not associated with mainstream publications have become media personalities as a result of the popularity of their blogs, or because their blogs covered major news stories before being picked up by the mainstream media. For instance, Matt Drudge of the Drudge Report gained attention because of the popularity of his conservative political blog, which broke major news stories such as initial allegations about the affair between President Bill Clinton and Monica Lewinsky.

Consumer Feedback

Facebook provides another way to disseminate information and create social networks, or overlapping systems of relationships that connect individuals with one another. Facebook allows consumers to "friend" media personalities. When they do so, content posted on Facebook by these media personalities appears in the newsfeeds of those who have friended them. These friends can choose to comment on posts with their content, to "like" the posts by clicking on a picture of a

thumbs-up, and to share stories and posts with other friends on Facebook. Thus, Facebook provides media personalities with a forum to post and respond to comments. Facebook also allows media personalities to share stories they like with their friends.

Twitter allows media personalities and consumers to send messages of 140 characters or less (tweets) to one another. Twitter, primarily aimed at mobile phone users, allows individuals to tweet their thoughts or to read the tweets of those they follow. By preceding another individual's user name with the "@" symbol, Twitter users can post a tweet directed to that user. By preceding certain words in their tweet with a "#," individuals hashtag information in a way that facilitates searches of that topic and allows Twitter users to determine what topics are talked about most on Twitter. For instance, a user could post a comment about the 2012 elections and include the phrase "#election2012." When another user searches for #election2012, all tweets containing this tag will appear in search results. If used by enough individuals, a hashtag may become a trend. Trends attract more individual users to hashtagged discussions because the hashtagged phrase appears within the Trending Topics area of a user's homepage.

Individuals can also retweet tweets made by others, sharing another's tweet with those who follow them. Media personalities routinely tweet their thoughts and impressions about politics in real time. For example, news consumers watching the 2012 presidential and vice presidential debates could not only tweet their thoughts about the debate while it was happening, but also read the tweets of their favorite political pundits. Many networks ran a constant stream of tweets about the debate on the screen as the political candidates debated. YouTube allows users to post videos that can be viewed by others. Media personalities can create "channels." Consumers can subscribe to these channels, following videos created or posted by the channel's creator. Individuals can also post video content with their favorite media personalities, sharing these videos with those following their channels. Like all other social media networking tools, YouTube users can post comments about the videos that they find on YouTube.

Many media personalities post stories and updates on social media sites like blogs, Facebook, Twitter, and YouTube. These social networking sites do more than provide news content. They also allow media personalities to enter into the social networks of consumers. Stories posted on these social networking sites appear in the Facebook and Twitter feeds of those who have “friended” or followed the media personalities. Individuals can also comment on videos shared on YouTube or posts made on blogs. These responses provide feedback to media personalities about their stories and updates. Media outlets use social media to attract consumers to their official Web pages from the social media pages of their personalities. Many news producers use applications on Facebook to create news pages for their major media personalities and the outlets on which these personalities appear. These pages provide basic information about news stories and hyperlinks that redirect users from Facebook to the social media personalities’ network Web sites.

For instance, the Cable News Network (CNN) television show *Anderson Cooper 360* has a Facebook page with basic information about stories that will be covered on the program and links to more detailed information that can be found on CNN’s Web site for the show. However, someone visiting the *Anderson Cooper 360* page on CNN also has the opportunity to share stories from that page with other members of their social networks via Facebook and Twitter. These attempts appear successful. Surveys suggest that a vast majority of users who follow news links on Facebook or Twitter also get news by going directly to a news organization’s Web site or using a news organization’s mobile phone app. The use of multiple types of social media by media personalities has become commonplace. The *New York Times*’ Nate Silver not only writes for the publication’s blog FiveThirtyEight, but also frequently posts comments to almost half a million followers via Twitter. The *Washington Post*’s Chris Cillizza also writes a political blog, The Fix, and communicates with over 160,000 Twitter followers.

Tailored Content

These types of social media allow consumers to receive information from media personalities outside of newspapers, magazines, and news

programs. For instance, consumers can now receive information from their preferred media personalities on Web sites like Facebook, or on their mobile phones via Twitter. They can also receive this information in real time. Content posted on Facebook, Twitter, YouTube, and other social media sites are instantly available to users. Consumers no longer have to wait until a newspaper arrives or a program appears on television to find out what their preferred media personalities have to say about political events. About one-third of Americans with smartphones go online, using their phones to view the news. Many of these mobile phone users download applications allowing them to use Facebook, Twitter, or YouTube on their phone. These applications allow individuals to see or share social networking content posted by media personalities virtually anywhere, anytime.

Social media also offers consumers much more control of content than old media. With old media, consumers had little choice in what stories they read or viewed. A viewer of live network evening news could not skip one story to view the next. Social media users can choose which media personalities they connect with via social networking sites. Users can choose whether to read posts or tweets. Users can also use social media to filter their news coverage, deciding what content to read or consider based on what others in their social networks recommend. Finally, social media users can also further spread the content posted by media personalities to others because things that individuals “like,” retweet, or post again appear in the personal feeds of other social network members who may not have friended or followed the media personality.

Social media provides its users with a much more interactive experience. Users may respond directly to content posted by media personalities via blogs, Facebook, Twitter, or YouTube. They may also share these comments or information found on other Web sites or social network sites with other individuals in their social network. For instance, Facebook users can embed a YouTube clip on their Facebook page for their friends on Facebook to see. This interactivity has made political information consumption a more social experience for consumers, allowing them to filter, digest, and react to news with other individuals within their social networks. Social media may

also expose new audiences to political media personalities. The audience for political news tends to possess certain demographic characteristics. One of the most prominent among these concerns age. Traditionally, young people have paid much less attention to politics than their older peers, and young people make up a substantial portion of social media users.

Recent research indicates that citizens use social media to receive political news, suggesting that political media personalities are wise to interact with consumers on social media sites. Approximately four out of 10 social media users say that these sites are important in helping them to keep up with political events. A quarter of social network users also say that social networking sites are important in allowing them to debate or discuss political issues with others, and the same proportion of individuals exposed to political content about a particular issue become more active on that issue after reading about it or discussing it on social media sites. Perhaps as important for media personalities trying to reach out to consumers, about a quarter of users say that social media sites are important in helping them find others who share their views about important political issues.

Yet, the extent to which political media personalities reach citizens via social media is limited. In 2012, only about 10 percent of Facebook users received any news from Facebook recommendations from news organizations or journalists. If media personalities reach social media consumers on Facebook, it seems much more likely that they do so through the recommendations of family members or friends outside of the political news industry. Political media personalities may have more luck reaching consumers on Twitter, where almost a third of individuals claimed to receive news directly from a journalist or news organization.

The reach of social media and the social media content posted by political media personalities, also appears quite limited. Those who use online social networks to learn about or discuss politics (political social media users) tend to have distinct demographic characteristics from those who go online, but do not use social networking sites for political purposes. In the United States, political social media users resemble the general population in terms of income, race, and gender.

Yet, these political social media users tend to be younger and more educated than the rest of the American population. Political social media users also tend to use technology more than other types of social media users. These political social media users are more likely to go online wirelessly from a cellular phone or laptop computer, to own a laptop computer, to have a high-speed broadband connection, and to use the Internet on their cell phones.

Those who use social media to obtain or share political content also tend to be politically interested. Those that post material about politics on social media Web sites often talk about politics with family and friends. These individuals are also more likely to have friends on social media who post about politics. Those who consider social networking Web sites important to their political knowledge and activities also tend to have distinct demographic characteristics. Democrats are more likely to identify social networking sites as important for political activities. African Americans and adults less than 29 years old are also more likely to say that social networking sites are politically important.

Echo Chamber Effect

A vast majority of social media users post little or nothing related to politics on social media Web sites. Only about one out of 10 digital news consumers obtain news on either Facebook or Twitter using a computer, smartphone, or tablet. Regular political social media users also seek out news elsewhere, making it unlikely that most are exposed to political information from media personalities that they would not otherwise see. Even if people obtain political information from media personalities via social media, it is unlikely that exposure changes their political views. Only a small fraction of social network users claim that they changed their views about a political issue after discussing or reading about it on social media.

Scholars also identify a number of negative effects that may emerge from media personalities' use of social media. The need to convey information in short entertaining fragments further exacerbates media's tendency to convey complex political information in sound bites, which lacking proper context, make it difficult for consumers to

gain a nuanced understanding of politics or political issues. Since consumers can tailor the news coverage they receive based on their interests and/or political beliefs, social media may also create an echo chamber where people only receive information that corresponds with their pre-existing beliefs and opinions. Also, because those who use social media to learn about politics tend to already be interested and active in politics, media personalities are not likely to educate politically uninformed consumers via social media.

These effects suggest that media personalities' use of social media may not have an entirely positive impact. Nevertheless, the use of social media by media personalities has had an impact on politics. Bloggers have broken stories and influenced the topics that mainstream media outlets cover. Social media, including Facebook, Twitter, and YouTube, have also eroded the barrier that traditionally separated media personalities from consumers, fundamentally changing how and when citizens receive political news.

Terrorism

A recent study by Gabriel Weimann of the University of Haifa found that nearly 90 percent of terrorist activities that are organized on the Internet are perpetuated through the various social media sites, with platforms like Twitter, Facebook, and YouTube used as a means of spreading terrorist propaganda, recruiting new members, and gathering intelligence. Social media have become a key component in the communication strategy of terrorist organizations. The cheap and easily accessible nature of social media offers terrorist organizations an efficient distribution mechanism, allowing them to reach a global audience with minimal effort. Additionally, because users of social media platforms self-select who they follow or receive messages from, social media platforms circumvent the gatekeeping of traditional mainstream mass media outlets, allowing terrorist organizations to directly interact with their target populations, removing the need for an intermediary in the form of news outlets as a means of releasing their messages to the public.

The idea that there is a symbiotic relationship between terrorist activities and the mass media is not new; terrorist organizations have long used mass media news outlets as a means of disseminating their messages to further their goals. While violent and aggressive terrorist acts have largely been ineffectual in forcing governmental change or the transfer of political and legislative power between factions, when it comes to the reporting of such events by news media, terrorist activities have proven effective in spreading the groups' political message and agenda to a global audience.

Mass media news outlets are silent partners in the terrorist process. Because of the highly

competitive nature of news media, media outlets rush to report on terrorist activities when they occur, which serves to perpetuate the goals, agendas, and messages of terrorist groups by promoting the event and message to a large (and often global) audience. Although mass media outlets may publicly condemn terrorist activities, they are by their very nature required to report on them, and in doing so they assist in the dissemination of the terrorist organization's message and agenda. The competitively charged atmosphere of the news media has made them vulnerable to exploitation and manipulation by terrorist organizations. One example of such exploitation and manipulation can be seen in the way that Osama bin Laden released audio and video threats to Arabic television networks, including Al-Jazeera. These media segments were then repeatedly shown on global television networks.

Use of Social Media

Of the terrorist groups currently in operation, Al Qaeda was one of the earliest to fully exploit the communicative and terrorist potential of the Internet. Brian Jenkins, a senior advisor for the Rand Corporation, notes that while Middle Eastern in origin, Al Qaeda has always viewed itself as a global movement with a global agenda, thus it has always depended on global communication networks to perpetuate their message to its target audience. Jenkins suggests that Al Qaeda leaders view communicating the group's message as the primary struggle. In addition to manipulating traditional news media, it has made extensive use of its Web page as a means of disseminating audio and video messages. Jenkins notes that the number of Web sites devoted to Al Qaeda as a political and religious movement has significantly grown, from several sites to several thousand.

Other terrorist organizations that have adopted social media platforms as a communicative strategy include the Taliban, Somalia-based Al-Shabab, and the Nigerian terror group Boko Haram. The Taliban Twitter account (@alemarahweb) has been active since May 2011, and now has more than 7,000 followers of frequent (and sometimes hourly) tweets. The terror cell Al-Shabab tweets under the handle @HSMPress, and has over 10,000 followers of its frequent tweets. Boko Haram uploaded a video statement on

YouTube in defense of its coordinated Christmas 2011 bombing attacks in Kono, Nigeria.

Discouraging Social Media Use

While a number of terrorist organizations have adopted social media platforms as a communication strategy, this use has not gone unnoticed by world governments. The U.S. government encourages social media companies to reject or remove content posted by terrorist organizations, a request that others argue contravenes the First Amendment, which protects freedom of speech. In 2008, Joe Lieberman and the U.S. Senate's Homeland Security Committee released an investigative report, "Violent Islamist Extremism, the Internet, and the Homegrown Terrorist Threat," which claimed that the Internet is a driving force in the terrorist threat to the United States.

The Homeland Security Committee continued to study social media use by terrorist organizations. In December 2011, the Subcommittee on Counterterrorism and Intelligence held a hearing titled Jihadist Use of Social Media—How to Prevent Terrorism and Preserve Innovation. Key witnesses testifying at the hearing included Brian Jenkins, a senior advisor for the Rand Corporation; Evan Kohlmann, a senior partner for Flashpoint Global Partners; William McCants, a senior analyst for the Center for Naval Analysis; and Aaron Weisburd, the director of the Society for Internet Research. In his testimony, McCants suggested that although terrorist organizations actively used social media platforms to promote their agendas and messages, research failed to show that their use of social media was effective in recruiting members, promoting their message, or fulfilling their overall mission. He further stated that closing user accounts for terrorist organizations would not be an effective strategy for stopping recruiting and radicalization, noting that this could put the United States at a disadvantage by reducing valuable intelligence regarding their activities.

Weisburd went further, suggesting that intelligence and security forces should not strive to remove terrorist groups from online platforms, but rather to deprive them of the branding that lends them an air of authenticity. He suggested that their use of social media was done in such a way as to allow them to brand their content, making themselves more visible and easily recognizable.

Additionally, Weisburd claimed that not only should terrorist groups be monitored, but that any organizations involved in any way in the production or distribution of terror group messages should be considered culpable, including Internet service providers (ISPs). Weisburd argued that ISPs should take responsibility for monitoring the actions of their users, without addressing the fact that current U.S. legislation forbids such censorship by businesses.

This viewpoint was rejected by Jenkins, who suggested that the potential risks associated with the online activities of terrorist groups should not be cited as justification for imposing stricter controls and sanctions upon content distributors like ISPs. He maintained that such attempts at content control at the server/ISP level would not be cost effective, and would ultimately render a valuable source of intelligence information unusable. Furthermore, he noted that there was no reliable evidence suggesting that such control of online content would be possible, a conclusion supported by earlier attempts by the U.S. and Australian governments at creating legislation for censoring Web site content deemed offensive.

Jenkins stated that while countries like China have been somewhat successful in monitoring and banning content deemed offensive, those countries have little concern for freedom of speech, a key foundation of the U.S. Bill of Rights. Additionally, he noted that shutting down one site would only drive terrorist groups to change names and move to another site or another social media platform, which would end up costing the government more money and staff time in tracking the digital trail.

Kohlmann argued for U.S. officials to apply more pressure to social media companies to remove content from terror groups, maintaining that while U.S. law offers few incentives for such companies to voluntarily turn over information regarding the illicit activity of their users, they must be held accountable for the perpetuation of hate speech by such groups. Between 2008 and 2011, the U.S. government made a number of requests of social media companies, asking that they remove content or accounts associated with known terrorist organizations; however, it was not until 2010 that some social media platforms began to comply with the request.

One of the earliest social media platforms to give in to government demands (from the United States, Chinese, and other governments) was YouTube, which in December 2010 changed its policy to allow for pulling video content posted by known terrorist organizations from its servers. In allowing for this removal of material, YouTube created a new category that allowed users to flag offensive content as “promoting terrorism,” a subcategory to their “violent or repulsive content” category.

Twitter has also amended its policy on censorship, following complaints and pressure from U.S. officials. Upon learning that Al-Shabab was using Twitter as a recruiting and propaganda tool, U.S. government officials demanded that Twitter executives close the account. Despite pressure from government officials, Twitter declined to shut down the account. However, in January 2012, Twitter announced a significant change to its policy, stating that it would begin censoring tweets in countries where the tweets could be seen as breaking local laws. This move drew significant criticism from Twitter users, who felt that the change was an attack on free speech and the open use of the Web.

In its defense, Twitter released a statement on its Web site that argued that various countries restricted certain types of content based on historical and cultural reasons, citing France and Germany’s bans on pro-Nazi content, and noting that prior to its policy change, the only way to deal with content deemed offensive in one country was to remove the content globally. The new change allowed the company to selectively restrict content from users in a specific country based upon government restriction agreements, while allowing it to remain visible to users from other countries. Twitter also announced that the content removal process would remain transparent, informing users of why the content was restricted or withheld.

Third Palestinian Intifada

In March 2011, the removal of a Facebook page calling for a third *intifada*, or uprising, in Palestine following a letter from Israel's Public Diplomacy and Affairs Minister to Facebook CEO Mark Zuckerberg caused controversy about the responsibilities of social media platforms in upholding certain types of speech. The call for an uprising came amid the ongoing demonstrations in the Arab world. The use of the term *intifada* was intended to evoke the First and Second Intifadas, uprisings by Palestinians against Israel that started as nonviolent demonstrations, but ended with significant casualties on both sides. The Facebook page, created in early 2011, called for 1 million people to join forces against Israel on May 15, 2011, and stated its purpose as being "against injustice, division, and corruption."

Given the violence of the First and Second Intifadas, the Israeli government moved to act against the Facebook page. Israel's Public Diplomacy and Diaspora Affairs Minister Yuli Edelstein wrote a letter to Facebook CEO Mark Zuckerberg requesting the removal of the page, which Facebook refused, stating that its policy is not to remove content that speaks out against "countries, religions, political entities, or ideas." The company spokesperson did, however, state that individual comments or posts considered "problematic" would be removed, and the page would be monitored.

As news of Edelstein's letter emerged, the page's administrators claimed that their page was being singled out among thousands of pages containing similar content, and threatened a Muslim boycott of Facebook if the page was removed.

On March 28, 2011, accounts of videos and images posted to the page disappearing began to emerge. The next day, Facebook removed the page, stating that while the company does not typically take down content that "speaks against countries, religions, political entities, or ideas," it monitors reported pages and removes them when they "degrade to direct calls for violence or expression of hate—as occurred in this case."

At the time of its removal, the Facebook page had amassed nearly 350,000 fans. While a number of Palestinian and pro-Palestinian groups expressed outrage at Facebook's action, several Israeli and pro-Israeli groups, including, notably, the Anti-Defamation League, praised Facebook's decision.

Although the original page was not restored, dozens of copycats cropped up in its place, many remaining after more than a year. This phenomenon, which occurs when attempts to hide a piece of information have the unintended consequence of publicizing the information more widely, is known as the Streisand effect, after an incident in which actress Barbra Streisand attempted to suppress photographs of her residence, inadvertently generating more publicity.

Responsibilities of Service Providers

The case reignited discussion of the responsibilities of online service providers in hosting controversial speech. While in the United States, service providers are allowed to determine what speech they

find appropriate, some scholars, such as Rebecca MacKinnon, have argued that the responsibilities of social media platforms need to be rethought in light of the fact that they are the primary locations in which online speech is conducted.

Other prominent cases in which political speech has been removed have occurred in Egypt, where prominent blogger Wael Abbas found his content removed from YouTube because it contained violent images of police brutality; and in Morocco, where in 2010 a group promoting atheism was removed from Facebook. In 2011, shortly after the Egyptian uprising, photo-sharing site Flickr (owned by Yahoo!) was also the target of anger after its staff removed photos of police officers that were taken from Egypt's raided state security apparatus and posted to the site. Yahoo!'s Business and Human Rights program blogged about the incident.

In the aftermath of the takedown, calls for a boycott of Facebook continued, though there appeared to be no effect if one occurred. Additionally, an American lawyer, Larry Klayman, filed suit against Facebook in Washington, D.C., Superior Court for \$1 billion, describing himself as an American citizen of Jewish origin active in "matters concerning the security of Israel and all people." The complaint called on the court to bar Facebook from allowing the page and similar pages that "advocate violence and death to Jews."

Facebook responded by saying that the case was without merit, and filed a motion to dismiss in late July 2011. In the motion to dismiss, Facebook called Klayman's monetary demand "outrageous," and cited the Communications Decency Act of 1996 (CDA), 47 U.S.C. § 230, which stipulates that an online service provider is not liable for most speech by third-party users. After Klayman failed to file an amended complaint, the lawsuit was dismissed without prejudice.

38Degrees.org.uk

38 Degrees is an online, multi-issue campaigning organization, based in the United Kingdom (UK), which emerged in 2009 and currently has over 1 million members. The organization was inspired by MoveOn in the United States, GetUp! in Australia, and Avaaz globally, and is founded on the same campaign model, commonly described as "digital activism," meaning using the Internet to mobilize people through campaigning. Groups such as 38 Degrees represent a challenge to traditional forms of political participation in that they are not directly involved with the state, and they are often critical of the state and corporate interests. 38 Degrees takes its name from the critical angle at which the incidence of a human-triggered avalanche occurs, which is meant to symbolize the power invested in mass mobilization.

The question of whether 38 Degrees marks a succinct break from traditional modes of political participation, or whether there are continuities, is important for the study of political participation. In terms of its organizational structure, 38 Degrees has attempted to avoid the concentrations of power and hierarchy that characterize formal politics. It presents itself as a decentralized and non-hierarchical organization, with its primary focus

to campaign on issues selected by its membership. The organization describes itself as nonpartisan and issue orientated, with a commitment to a progressive agenda, which seeks to: “campaign for fairness, defend rights, promote peace, preserve the planet and deepen democracy in the UK.” 38 Degrees has its physical headquarters in London, comprised of a small core team of paid and voluntary staff, headed by Executive Director David Babbs. It also has a board that advises on campaigning and financial matters. While originally dependent upon donor contributions, the organization is now largely funded through membership.

Under the motto “people. power. change.” 38 Degrees argues that it “puts power into people’s hands by giving members ‘a new way to be involved in politics,’ with the ultimate aim of strengthening democracy.” Online technology is critically important to the new method developed by digital activists such as 38 Degrees. 38 Degrees uses the Internet and social media to mobilize, coordinate, communicate, and build community among its membership. Like GetUp! and MoveOn, 38 Degrees’s core tactic for campaigning is mass e-mail, although social media platforms such as Facebook, Twitter, and blogs are also used to promote campaigns. Online tactics are supplemented by offline methods, such as telephoning or writing to a member of Parliament (MP), meeting with MPs, and organizing local meetings.

The 38 Degrees Web site has three main functions: offering members actions for mobilization, polling members about which campaigns 38 Degrees should champion next, and providing information about the progress of campaigns. Enabling members to vote for which campaigns to pursue ensures that campaigns are member-led, which is central to their campaign model. This aim is also achieved through the “Campaigns by You” section of the Web site, which allows members to initiate new campaigns and act as the contact and executor of the campaign.

Stand up for the NHS, Spotlight on Tax Dodging, and Save Our Forests are all examples of 38 Degrees campaigns. The success of campaigns is measured through achieving stated aims and raising awareness of issues. As an example, the Save Our Forests campaign was a response to the UK government’s plans in 2010 to sell off publicly owned forest and woodland in England. In response, 38

Degrees coordinated a series of actions, beginning with an online vote on whether 38 Degrees should develop a campaign on the issue. Following a positive response to this question, key actions included: an online petition, members donating to fund a YouGov poll, e-mails and calls to MPs, and ads in national newspapers. Additionally, local groups around the country campaigned, and members shared the campaign on Facebook. As a result of its actions, 38 Degrees claims to have succeeded in persuading the UK government to drop plans to privatize England’s forests.

Forms of Political Participation

The emergence of 38 Degrees must be located within a broader context of debates on declining levels of political participation in the UK and beyond. In Britain, voter turnout at general elections has steadily declined, and this pattern is broadly replicated across the world in countries where voting is not compulsory. In a similar vein, all three main UK political parties have experienced a dramatic decline in membership levels since the 1960s. These concerns have led authors such as Robert Putnam to argue that political apathy is increasing, and that democracy is at risk. An alternative interpretation is that the decline in traditional forms of participation must be situated within a broader understanding of the rise of alternative forms. Accordingly, people are not apathetic and disillusioned with politics in general, but with formal politics, and seek new modes of expression. The group 38 Degrees offers one such avenue.

The popularity of 38 Degrees as an online platform for political mobilization is evidence that there has been a change in the types of political actions in which individuals are engaging, a point made by Pippa Norris. Drawing on extensive analysis of social movements, Norris argues that political participation has diversified in terms of changes in the agencies (the collective organizations through which people mobilize), the repertoires (the ways in which they choose to express themselves), and the targets (the actors toward whom participants are attempting to direct their action) of political participation. 38 Degrees is an important new agency using new repertoires, but its main focus is on influencing government.

With declining levels of formal political participation, it may be tempting to posit a radical

change in forms of mobilization. Stuart Shulman and Micah White, however, suggest caution in this view, and argue that clicktivism, or digital activism through mass e-mailing, requires minimal engagement effort and has negative long-term effects for citizen engagement because authorities learn to ignore such tactics and they crowd out more substantive participatory efforts.

In contrast, David Karpf suggests that online mobilization is, for many, a first step on a ladder of engagement. In addition, he argues that mass e-mail is often one strategy among many, and that digital activists also employ many offline strategies. This is true for 38 Degrees, and was also found to be the case by Ariadne Vromen and William Coleman in their research on GetUp! State and formal politics remain central to this model of political participation, which suggests that 38 Degrees' aim is not to reject formal politics, but to improve it through enabling greater participation and reconnecting people to government.

Thune, John

When John Thune's name was raised as a possible Republican candidate for the presidency in the run-up to the 2012 election, few Americans had heard of him. But the South Dakota senator was well-known in political circles for his historic defeat of Senate Minority Leader Tom Daschle in

the 2004 election, in which he was one of the first successful candidates to lean heavily on social media in his campaign strategy.

John Randolph Thune was born on January 7, 1961, in Murdo, a small town in the most sparsely populated part of South Dakota, where his paternal grandfather, a Norwegian immigrant, owned the Thune Hardware Stores chain. An accomplished high school athlete, Thune played basketball at Biola University in California, from which he graduated in 1983 with a bachelor's degree in business. An M.B.A. followed a year later from the University of South Dakota. After college, he worked for Senator James Abdnor, a Republican who in 1981 had defeated Democrat George McGovern, then one of the pre-eminent liberal icons in American office.

Thune then worked for the South Dakota Republican Party, serving as its executive director from 1989 to 1991, and for the next few years had various jobs in politics and civil service. He first ran for office in 1996, at age 35, and was elected the congressman from South Dakota, arguably a significant role in a state with only one representative.

Thune was successfully re-elected twice by significant margins, and resisted suggestions to run for governor, instead unsuccessfully challenging Senator Tim Johnson in 2002. When Daschle, then the Senate Minority Leader, announced he would not run for president in 2004, Thune ran against him for his senate seat in 2004. The country was in the midst of the George W. Bush presidency, with many expecting that a Democrat would defeat Bush's re-election efforts. The PATRIOT Act and the wars in Iraq and Afghanistan were key areas of dispute, despite having received bipartisan congressional support in the heady months following 9/11. The race between Thune and Daschle became the most expensive in South Dakota history and the most expensive Senate race of the election cycle, with \$30 million spent overall. Thune wound up winning with 51 percent of the vote. Daschle was the first senate leader in over 50 years to lose re-election. Thune subsequently won re-election in 2010, running unopposed.

Social media was key to Thune's campaign, and while at first glance this may seem unexpected for a rural senator, the rurality of Thune's constituency was exactly his reason for relying on social

media. Though South Dakota is the 17th-largest state, it is the fifth-most sparsely populated. South Dakotans are less likely to have access to face-to-face time with candidates than small states like New Hampshire or densely populated states like Maryland. Vigorous use of social media allowed Thune to communicate with South Dakotans, to convey his views, to respond in real time to issues brought up by the Daschle campaign or the media, and to monitor the issues South Dakotans were talking about online, in order to adjust his campaign and media strategy. He involved bloggers in his campaign efforts, interestingly doing so at a time when ultraconservative pundit Glenn Beck was especially critical of blogs as appealing only to fringe elements and anonymous attackers.

Jason Van Beek's South Dakota Politics blog (home to a "Kranz Watch" feature criticizing Sioux Falls Argus Leader political reporter David Kranz) became the center of the Dakota Blog Alliance that formed in the spring of 2004, and for which the Thune–Daschle race provided considerable material. The Daschle campaign was never quite able to figure out how to handle blogs; Thune, on the other hand, proved able to turn their antimass media sentiments to his advantage, since the journalistic mainstream of South Dakota had a long history with Daschle. Two bloggers were hired by the Thune campaign, and paid a total of \$35,000 to attack the election coverage of the Sioux Falls Argus Leader, which both influenced the Argus Leader's coverage and discredited much of its support of Daschle. Notably, Kranz had previously worked for Daschle, a connection the bloggers played up in their discrediting efforts.

As senator, Thune has been an active proponent of gun rights, wind energy, and ethanol subsidies, and as the Republican Conference Chairman, he is the third-highest ranked senator. Though he wound up not running for president in 2012, despite widespread speculation and the support of Republican leaders in the Senate, speculation continues to center around a 2016 presidential race. He continues to use social media in his outreach to his constituency, and is personally involved in running his social media accounts.

Topology of Social Networks

Social networks can be defined as the systems of grids, lattices, and ties that create, shape, and maintain the relations between individuals. There are different ways of classifying social networks, taking various factors into account. One of the ways is to classify social networks according to their cohesion and complexity. In this case, the classification of social networks into loose networks and dense networks is applicable.

Another factor that can be used in typologies is propinquity. Networks discussed by taking the notion of nearness into account can be categorized by geographical or mental closeness. The next notion is homophily. Homophilous networks encompass users who are similar in terms of origin, gender, education, interests, and knowledge. The common feature was the deciding factor in their selection of networks. Thus, homophilous networks are popular when people want to

exchange knowledge with people in possession of similar skills or profession. The mentioned similarity is treated as the factor guaranteeing the level of discussion and credibility of information sources.

The next type of networks are heterophilous networks that attract individuals who do not possess exactly the same skills or expertise, and may vary as far as such features as education, gender, or social status is concerned. The aims of these networks are as follows. First of all, such networks allow for knowledge exchange between people of different backgrounds and skills. In this case such networks stimulate information flow between people having different expertise on the discussion topic and different attitudes to the discussed issues. Additionally, such networks as linguistic homophilous and linguistic heterophilous networks can be observed. Homophilous linguistic networks rely on common code, and a convergent communication style is adopted to foster information flow.

On the other hand, heterophilous linguistic networks aim at showing independence, uniqueness, and so on. The aim of divergence is to differentiate oneself from the group. Another issue in social networks is mutuality, which stresses the notion of reciprocal relations and little power or asymmetry. This approach allows one to divide organizational networks into employee networks and employee–employer networks, as well as classify family networks. Moreover, social networks can be divided into ego-centric, sociocentric, and open-system networks. Ego-centric networks are the ones connected with a single node, sociocentric networks reflect the connections in a closed system, and open-system networks encompass relations in networks of unfixed boundaries.

Organization

Social networks can also be divided according to how they are run. Thus, self-organizing networks do not require steering, whereas directed networks are controlled. Social networks are also divided according to the age of their members such as children's, teen, and senior networks. Apart from age, social networks are related to some stages of life (e.g., student networks, expatriate networks, pregnancy networks, or parent networks). What

is crucial in such networks is the temporality of engaging in such networks. For example, most pregnant women do not continue discussion in such networks after they become mothers. Networks may also transform from a temporary to a more fixed network, such as from expatriate networks and migrant workers networks. Gender or sexual preferences can also determine social network formation. Social networks can be investigated by examining the purpose of their creation and development. The following networks can be observed: relation networks, knowledge networks, innovation networks.

Purpose

Another important factor to take into account is the reason for a social network's creation. For example, social networks are created to keep people of similar origin in contact when the primary reason for their staying together does not apply any longer, such as with alumni networks. Social networks can also be classified by taking into account the sphere of life they are related to. For example, health networks (such as cancer or diet networks) are created for information and support. Social networks can also be classified by stating the entry conditions. Networks are classified by privacy and entry conditions are concerned. Thus, some social networks are free, whereas others are closed, being directed exclusively at a certain group of people. Taking into account the last factor, general networks and elite networks can be examined. Moreover, the law can also determine network formation, by dividing networks into legal and illegal networks. Networks can be also viewed from the legal perspective where the division of legislative or policy networks applies.

Other Characteristics

As far as geographical differences are concerned, urban and rural networks can be observed. Networks can be divided by taking into account family relations and kinship networks. Apart from family, there are also hobby networks that gather individuals interested in specific leisure activities. Network types are also related to the vocational sphere of life, with professional networks, such as scholar networks and teacher networks.

Another characteristic to consider is scope. Thus, at the microlevel, individual networks are investigated. Other levels are constituted by organizational and government networks. Then there are regional, international, or global networks. Networks can also be classified by taking their duration into account. For example, project networks are temporarily formed for task completion. Moreover, social networks can be classified according to the relation between entities. Vertical networks encompass diversified stakeholders, whereas horizontal networks involve people or entities at the same organizational level, that is, having the same position in a company, or offering similar merchandise.

Networks can be of internal and external character, being within or outside the organization (inner organizational networks and outer organizational networks). For example, interdepartmental networks are an example of inner networks. Networks can be also classified by taking the material focus into account: for-profit and nonprofit networks.

Social networks can be divided by taking into account different perspectives, such as customer or user perspectives. In the case of organizations, consumer, patient, and student networks can be observed. Networks are also determined by the national culture of their users. Thus, in some countries more collaborative networks or more transactional networks can be observed. Taking the level of formality into account, social networks can be divided into formal and informal networks. Moreover, social networks and their types can mirror political and historical circumstances. Thus, one may deal with opposition networks, antiwar networks, repatriate networks, or human rights networks.

Politics

Online social networks take advantage of the speed, reach, interactivity, and low cost of social media. These features determine both upward and downward communication in politics. Thus, politicians can quickly reach many potential voters, supporters, or opponents. At the same time, social media give an audience the opportunity to take part in political discussions, exchange opinions, offer support, or express dissatisfaction. Social media centered around politics do not exist

in a vacuum, but instead constitute a part of the broader system of social networks.

Social networks in social media can also be characterized by taking into account their durability. Thus, fixed online networks and temporary online networks could be investigated. Temporary networks are often created in the advent of sudden and unexpected need, such as risk or crisis situations. They are used by politicians to respond to unexpected situations. As far as online social networks and participation forms are concerned, asynchronous and synchronous networks can be examined. In asynchronous online networks, people are given time to become acquainted with posted information, whereas synchronous online networks require immediate response.

Tor

Tor, originally an acronym for "the onion router," is open source software that facilitates anonymous

use of the Internet. Onion routing is an encryption service based on David Chaum's mixed-network technique that sends data through a series of proxy servers. These proxies function as intermediary nodes, or onion routers, where data is encrypted. Data is re-encrypted at each successive node, resulting in multiple layers of encryption. This technique makes it difficult for those conducting surveillance or traffic analysis to determine the source, destination, or contents of a message. The Tor Project is a nonprofit organization that has been responsible for onion routing software development and education.

Tor has become a subject of popular notoriety since Bradley Manning (now Chelsea Manning) was discovered to have used the software in acquiring and leaking classified materials to WikiLeaks, including the Afghan War Logs and the *Collateral Murder* video. Dissidents across northern Africa and the Middle East began using Tor to anonymously organize mass protests and political action in the Arab Spring. Detractors of Tor describe it as a tool that enables illegal activity to more easily thrive online. Whether one supports it as increasing user agency, or decries it as a criminal weapon, Tor is a site at which debates concerning surveillance, control, and anonymity play out in a tangible way.

Like Internet working technology, Tor originated as an intelligence tool of the U.S. military. The U.S. Naval Research Laboratory (NRL), with the support of the Defense Advanced Research Projects Agency (DARPA), charged Paul Syverson with leading a team to develop onion routing software. Syverson successfully recruited Roger Dingledine and Nick Mathewson, recent graduates of the Massachusetts Institute of Technology (MIT), who had been involved in developing an anonymous data storage system called Free Haven. Because the Free Haven system functioned through a distributed, anonymous, decentralized peer-to-peer network structure, Syverson saw Dingledine and Mathewson as good candidates for the job. While the team had established a functional onion routing network by 2002, it was not until 2004 that they announced the availability of Tor as second-generation onion routing software. Diverse groups began accessing the Internet through Tor all over the world, including militaries, law enforcement agencies, businesses and corporations, leakers, whistleblowers, activists,

citizens living under repressive regimes, and ordinary users concerned with maintaining privacy. This broad adoption of Tor is not at odds with its origin as an intelligence tool of the U.S. military. By virtue of its decentralized and distributed structure, Tor must be used by a diverse group of actors for anyone to maintain anonymity.

Support

In addition to DARPA and the NRL, the Tor Project has received financial support from a diverse group of organizations. From 2004 until 2005, the Electronic Frontier Foundation (EFF) offered Tor additional support and publicity. The EFF, an international digital rights advocacy group, provided Tor with popular legitimacy among politically minded Internet users. Other organizations that have funded the Tor Project include the National Science Foundation, Human Rights Watch, Google, and the Swedish International Development Cooperation Agency (Sida). Perhaps the most surprising sponsor of Tor is the Broadcasting Board of Governors (BBG), which has recently been the most generous donor. The BBG was formed in 1999 as an independent agency in charge of all nonmilitary international broadcasting sponsored by the U.S. government. The BBG is responsible for broadcasting services including Voice of America, the Office of Cuba Broadcasting, Radio Free Europe/Radio Liberty, Radio Free Asia, and the Middle East Broadcasting Networks. A large portion of these broadcasting services' intended audience is subject to government censorship. The BBG sees Tor as a powerful tool through which Internet users can circumvent government censorship, increasing the audience of U.S. government broadcasting internationally.

The most visible spokesperson for Tor is Jacob Appelbaum, a core member of the project, who is also the only American member of the WikiLeaks team. Under the leadership of Julian Assange, WikiLeaks is widely believed to have siphoned over a million documents from the Tor network, including some stolen by Chinese hackers and spies, before the site was even launched. Following Bradley Manning's use of Tor to submit the Afghan War Logs to WikiLeaks, Assange, fearing arrest from the U.S. government, chose to cancel a trip to New York City where he was scheduled to give a talk at the 2010 Hackers on Planet

Earth conference. He asked Appelbaum to take the stage in his place, representing WikiLeaks and Tor in tandem. Since that time, Appelbaum has consistently travelled the world as an outspoken advocate of anonymity, regularly publicizing his subjection to what he claims is systematic harassment by the U.S. government.

Political and Illegal Usage

Egyptian dissidents used Tor to circumvent government surveillance during the overthrow of Hosni Mubarak's regime early in 2011. Social media, including Facebook and Twitter, allowed protesters, activists, and revolutionaries to organize and publicize political action on a global scale, spurring the popular media to refer to the Arab Spring as the "Twitter Revolution." The use of Tor was less widely reported. When the Mubarak regime began to block sites such as Facebook and Twitter, for example, Tor witnessed an exponential increase of downloads from the region as Egyptian citizens accessed the Tor network as a proxy for their Web browser. Tor allowed dissidents the continued use of the Internet as a tool of political action, even though popular social media sites were blocked.

Tor has been used to facilitate criminal activity. For example, the onion network has become a preferred method for distributing and acquiring child pornography. In 2010, hacktivists working under the banner of Anonymous carried out Operation Darknet, conducting distributed denial-of-service attacks on a child porn site called Lolita City. This operation brought to light the dark underbelly of the Tor network. The network is also home to an anonymous marketplace called the Silk Road, where illegal drugs are exchanged via Bitcoins, a digital currency that is encrypted and provides strong anonymity. The popularity of Tor points to sociopolitical anxieties concerning surveillance, privacy, and control. The software, used for good or bad, facilitates the strategic deployment of anonymity, which has become a primary means to increase agency while online. Tor does not only facilitate anonymity; the software has also become a site of contestation, where competing discourses over the political role of the Internet and social media clash.

Launched in 1995, Townhall.com is a conservative online publication providing commentary and analysis; U.S. and world headlines; entertainment, health, financial, science and technology, religious, and political news, and conservative opinions from more than 250 columnists. The site's columnists have included Neal Boortz, Ann Coulter, Dinesh D'Souza, Larry Elder, David Limbaugh, Michelle Malkin, Michael Barone, Star Parker, Dennis Prager, John Stossel, and Thomas Sowe. Opinion leaders and researchers from many conservative partner organizations contribute to the site as well. According to its Web site, Townhall.com is designed to "amplify those conservative voices" in political debates.

Townhall.com also acts as a media center for conservatives to engage in politics through other forms of media, such as talk radio and magazines. Townhall talk radio offers daily commentary, a weekend journal, news via podcasts, and online streaming through affiliated radio stations owned by Salem Radio Network. *Townhall Magazine* is a monthly news and opinion journal featuring in-depth interviews, investigative journalism, and research analysis by right-wing reporters, opinion leaders, and political insiders.

In 2006, Salem Communications acquired Townhall.com, and in 2010, it also purchased Hot Air, which is a continually updated blog that features political and cultural analysis from the center

to right perspective. Commentators for Hot Air include well-known conservatives such as Rush Limbaugh, Sean Hannity, and Laura Ingraham.

Traditional forms of media have seemed to be separated from society and culture, reporting on news from a nonpartisan position. As scholar Jason Wilson has written, a minority of citizens are attracted to and emotionally involved in the spectacle of mediated politics. Unlike traditional forms of media, new forms of social media encourage commentary from laypersons and experts alike. These media tools are relatively unrestricted compared to traditional mass media outlets. Therefore, participants can immediately shift the conversation and influence the political platform in a manner that traditional media outlets cannot. Townhall.com is a media hub where conservative voices can engage in dialogue, making it an influential political tool. According to experts on social media and politics, the use of social media tools allows “political fans” to participate in platforms and practices, contributing to live commentary on political broadcasting.

Through the implementation of new forms of social media, Townhall.com is contributing to the phenomenon labeled political mediatization. Mediatization is a theory used to describe the influence that the media has on society and culture, acting as agents of change. Mediatization describes the impact of the media on various institutions; however, it is not a universal process—only Western societies are affected by it. According to this theory, mediation occurs in four phases. The initial phase of mediatization is the degree to which the media constitutes the dominant news source. The degree to which the media is independent from the governance of political institutions is the second phase. The third and fourth phases consist of the degree to which media is governed by political or media logic, and the degree to which political actors are governed by political or media logic.

At the time of Townhall.com’s launch, there were only a handful of political Web sites in existence. For the past 15 years, Townhall.com has been providing conservatives with the opportunity to engage in the political process with “unprecedented ease,” and has become an important part of the nationwide political discussion.

Traffic Analysis

Because the Internet has become a key factor in the information and communication society, the analysis of traffic generated through this medium is particularly important for different uses. Traffic analysis is a concept with multiple definitions in the field of computer networks, from military and security applications designed to avoid national communication system attacks, to commercial applications with the main goal to measure the number of users who visit a Web site for advertising and commercial reasons. It is of great importance to those who seek to not just understand, but also affect political issues and election outcomes, with success predicated on an accurate reading of the appropriate pulse in any number of body politics. One of the concerns of computer security is traffic analysis in the context of military intelligence or counterintelligence. Thus, there is a special technique of attack that involves interference patterns of communication between the different entities of a system.

Traffic analysis is a process of intercepting and examining messages through communication patterns, from which one can deduce the information they contain. This technique can be applied even though messages can be encrypted and decrypted. The traffic deduction will be easier the higher the number of messages observed, intercepted, and stored. In fact, it will allow knowledge of who the subjects of communication are, when it occurred, and for how long. Other information that may be useful in this attack technique is the size of the packets exchanged between two communicating hosts, even without access to the content of it, either because it is encrypted or not available. Thus, one can deduce that there is an interactive session between two hosts from a short burst packet payload byte (each packet indicates a single key), with subsequent pauses between each packet. By contrast, large packets sustained over time can indicate the transfer of files between computers, further indicating which host is sending, and which host is receiving the file.

This information does not have to perform terribly harmful activity to the security of the network, but creative attackers will be able to combine this information with other information to elude the safety mechanisms. At the same time, it is necessary to highlight that traffic analysis can also be used as a defensive technology by identifying anomalies in traffic patterns. Administrators can use traffic analysis to baseline the traffic to and from hosts on the network for a period of time and display the information in a graphical format (e.g., line charts or other graphics). As a daily routine, the administrator can review this information and compare the patterns of network activity to and from hosts and networks, including the number of packets, packet sizes, use of bandwidth, and connections per hour.

Traffic Analysis and Commercial Uses

Another definition of the concept is used to measure the amount of data sent and received by the users of a Web page. The traffic of a Web site is determined by the number of users who visit a page, and the type of content they visit. Traffic analyzes pages for their popularity. The most visited sites become a major attraction for advertisers, which are the basis of the business model of most Web pages. Web traffic can be analyzed through

the data that is stored on a server that is hosted on the page, which automatically generates a listing of the spaces that have accessed the Internet, the content downloaded, and the time visitors have spent. When a user requests a Web page from the server, it generates a hit. That is an “impact,” or a visit to the Web site. The server performs a hit for each time a visitor views text and graphics on the site. A page with five images will make a hit with the text of the Web site, and another five for each graph. So, the total number of hits of the Web site is six (raw access), although advertising only takes into account one (net access). The visitor will always generate at least one pageview (front), but can generate many more. There are also external applications that make Web sites record data by inserting a metatag (small HTML code) on every page of the site. Web traffic is also sometimes measured by packet sniffing, and also delivers random traffic samples and external information, particularly on the use that the Web page has on the Internet.

The main parameters measured to analyze the traffic of a Web site are number of visitors, average page views per user, average time of a user on the site, average page duration; dominant classes (levels of IP addresses required to open Web pages and content), the prime time, most requested sites, and covers most requested (the first page of the site, which attracts more visitors). The amount of traffic on a Web site is a measure of its popularity. Analyzing visitor statistics is useful in order to know what is working and what should be improved on a Web site. Traffic data can also help to increase (or in some cases decrease) the popularity of the site and the number of people who visit.

There are numerous free tools to measure the traffic on Web sites. Alexa is one of the most popular services. It generates Internet traffic statistics and Web site rankings based on people who access Web pages using the Alexa toolbar. It also provides data on percentage of users by country, keywords that are well positioned in search engines, and sociodemographic data. URL Trends offers the user the possibility of checking statistics. BizInformation is another provider of traffic statistics. In addition to providing data such as social bookmarking, Web recognition, and social metrics, BizInformation allows one to know the value of a Web site in economic terms. Google

Analytics is one of the most popular services. It is part of the free tools provided by Google. It is a traffic analysis service that allows monitoring of the Web both qualitatively and quantitatively, during a period of time, from different sources, including search engines, third-party Web sites, direct traffic, and traffic that comes from a campaign such as AdWords (sponsored keywords from a marketing campaign in the pages of the Google search results).

Political Uses of Traffic Analysis

Traffic analysis is also used for political and electoral purposes. Many countries, especially those with dictatorial governments, use monitoring tools on Internet data traffic to censor certain Web content and monitor communications of political opponents, activists, and journalists. The presence of this type of tool in countries where they violate human rights is disturbing because this kind of censorship isolates the population and contributes to maintain dictatorships because of the lack of external information. From the electoral point of view, analyzing and controlling Web traffic can help empower governments by spying on insider opponents. Although these traffic analysis uses violate fundamental rights, democratic governments normally use these tools for filtering viruses and prosecution of crimes such as child pornography distribution.

Transparency

The concept of transparency refers to an open administration of the *res publica* (literally, "the public thing," that which concerns everybody and which belongs to the public). Transparency guarantees citizens the ability to control both state institutions and elected representatives through enhanced monitoring and whistleblowing structures, providing space for the punishment of attitudes that harm the public interest.

Nadia Urbinati argues that visibility (which leads to more transparency) is fundamental to democracy because it provides citizens with a powerful weapon that goes beyond the ability to express opinions freely, or even the chance to vote in clean and fair elections. Therefore, being clear about what is happening inside the structures responsible for the decision-making process makes it possible to establish a unique type of control over public affairs.

On one hand, it is known that many contemporary transparency initiatives necessarily use mass media resources. Due to factors such as geographical distance, there is no way to directly monitor the activities of political representatives. Moreover, it has become impossible for citizens to access, filter, and interpret the vast amount of data concerning the administration of public affairs.

On the other hand, the diagnosis carried out by a number of researchers indicates that one of the reasons for citizens' alleged distrust of politics has grounds in the inefficient communications strategy maintained by state institutions. Accordingly, an essential step in order to increase transparency would be to ensure that information flows through various channels with good quality and depth.

Digital Media

It is precisely at this point that expectations arise about the contribution that digital communication could offer for improving transparency mechanisms. According to Herwig Ostermann and Roland Staudinger, as well as John Carlo Bertot, Paul Jaeger, and Justin Grimes, the repositories of information offered by digital media reduce the costs of collection, storage, distribution, access, and filtering of government information.

Among the various digital communication media, social media have gained attention in

recent years. Interaction is key to such platforms, since they are based on the concept of Web 2.0. Indeed, for many scholars, the use of social media presupposes the opportunity for users to contribute to the production, dissemination and, naturally, consumption of information.

A significant part of research into the Internet and democracy finds that social media offer a distinct advantage for improving transparency mechanisms. For John Carlo Bertot, Paul Jaeger, and Justin Grimes, such an argument is based on valuing four points: collaboration, participation, empowerment, and time.

Three kinds of resources can be perceived as the main social media used to foster transparency:

- *Blogs*: Government agencies worldwide have used blogs in various ways. However, in certain cases, depending on the openness of each institution, blogs provide only unidirectional information, without opening up space for interaction with users. Sometimes, citizens create “mirrors” of official blogs (keeping the content the same), with the differential of providing space for comments, which indicates a singular appropriation of these initiatives originally created by governments.
- *Wikis*: By using wikis, users can, for example, collaboratively draft laws. After discussing the need to create a new law, an outline of the project is submitted to the public. Each citizen can propose new paragraphs, as well as rewriting or suggesting the elimination of parts of the project under discussion. The tracking of changes is an additional element to ensure internal transparency of the collaborative process. A separate page serves as a space for discussion of each item of the project, promoting what contemporary political theory literature has identified as “public deliberation.”
- *Social network sites* (SNSs): These are platforms that connect users who share affinities. They allow a rapid exchange of information (usually messages without many words). SNSs indicate the possibility of establishing a more egalitarian relationship between users, since open

profiles (e.g., on Twitter) can be freely mentioned and provoked into responding to demands addressed by unknown users. There is no guarantee, however, that all agents involved in the interaction are willing to exchange ideas or respond, once they are triggered.

Challenges

Despite the undeniable potential of social media, a number of the difficulties that characterized the performance of earlier digital communication platforms still persist. At first, one can identify problems related to the political and institutional context of every democracy. To Bertot, Jaeger, and Grimes, the factors that may hinder the adoption of social media in order to promote transparency range from citizens’ traditional distrust of institutions (as John Gastil mentions) to the difficulty in making state agents accept changes in the political culture in which they operate because transparency demands bureaucratic organizations to take on new behavior.

Additionally, it is essential to adopt access to information laws, which, among other provisions, stipulate the response time to demands made by users and set the pace for updating data. A privacy policy intended to protect users each time they request information is also essential, as there is no clarity about the increasing amount of data that states hold on citizens.

Second, it is essential to consider factors specifically related to the use of digital communication technologies. The language employed in the experiments aimed at making the work of the state and its representatives more visible needs to be simple and straightforward. According to Dieter Zinnbauer, an essential step is to make tutorials available that are aimed at explaining to citizens how to find and acquire the data that they need. In addition, the importance of improving the navigability of Web sites and promoting alternative low-cost Internet connections should be considered. Another critical step, also suggested by Bertot, Jaeger, Sean Munson, and Tom Glaisyer, refers to the integration of the communication systems of government agencies, such as creating an apparatus for searching for and retrieving information in order to facilitate monitoring of public spending, for example.

Even while praising the need for transparency, Nadia Urbinati warns that visibility does not necessarily guarantee that citizens will see what really matters. That is, the mere provision of more data on the state's performance can represent virtually zero gain if the information available is of little relevance. Besides, as Ed Felten points out, it cannot be forgotten that there is the possibility of governments using digital mechanisms only to promote their own public image and to create an aura of legitimacy, but without presenting relevant information.

Ultimately, Kevin Marsh's argument gains strength when he states that the mere provision of more services and information does not guarantee an automatic solution to the problems that affect democracies, such as corruption. Transparency is only one of the dimensions to be considered in order to improve democratic practices.

An Occupy Washington, D.C., protester advertises the "OCCUPY" Twitter hashtag during a street action on October 6, 2011. Trending topics on Twitter may quickly disappear, with 13 percent of the top 1,000 usually turning over every 24 hours.

frequently recurring words or phrases on the site. Some conversations get marked with a hashtag, or a # sign in front of a word or series of words without spaces. Users wishing to join a conversation, for example one about an Occupy protest, might include "#occupy" as part of a tweet. If enough users include the hashtag in their tweets, then it might become a trending topic. Also, users wishing to build interest in a topic might quote or retweet another tweet.

Started in summer 2008, trending topics appear in a sidebar on the main Twitter site. Users without a geographical preference in their profiles will see the global trends, while users with settings limited to countries or cities will see the top trends in those areas. By clicking on a listed trend, users can read what other users are saying about it.

Trending Topic

A trending topic is a general idea that gains popularity for a brief period on the microblogging Web site Twitter. Trending topics draw from

Content of trending topics widely varies. News events that receive global attention become trending topics. For example, when the earthquake and subsequent tsunami hit Japan in 2011, the topic “#PrayforJapan” quickly grew in popularity as people expressed their concern. Celebrity deaths (both real and fake) also become trends. The unexpected death of Michael Jackson became a trend in 2009, while several still-living celebrities experienced “hoax deaths,” including Paul McCartney, Morgan Freeman, Jim Carrey, and Lindsay Lohan. Living celebrities become trends, particularly singer Justin Bieber.

Other trending topics become more like memes, which bring together people sharing viewpoints on particular cultural ideas. Tweepsters will include the hashtag of the meme, and then add their ideas toward a site-wide conversation. Most memes center on personal opinions, such as “#ThatsSoAttractive” or “#iwish.” Some memes receive strong backlash for their racist and/or sexist implications, such as “#hoodhoe” and “#whatmakesablackgirlmad.”

Trending topics are intentionally used, however. Some trending topics are “promoted,” in which a company pays to have its products or services featured at the top of a trending list. Pixar bought the first one in order to promote the release of *Toy Story 3* in 2010. These promoted topics appear on all pages. Other purposes start with raising awareness, such as the wearing of a black-hooded sweatshirt in memory of Trayvon Martin or the police and protester clashes during Occupy protests around the world.

Twitter uses an algorithm, or a mathematical computer formula, to identify topics that quickly gain popularity, with emphasis on the immediate over the long term. The topics churn, or change, very quickly. Topics that appeared as the top 10 list one hour might change within the next hour, with about 17 percent of the top 1,000 changing within that period. Across a 24-hour period, about 13 percent of the top 1,000 topics disappear. Search queries based on key events, however, cause spikes that supersede these data. Steve Jobs’s death, for example, resulted in a 15 percent spike.

Aside from promoted trending topics, the primary influence on trending topics comes from mainstream media outlets, such as the *New York Times* or the *Huffington Post*. These outlets start

72 percent of trending topics, which reinforce mainstream agendas. Without the popular press backing, and even with Twitter users’ backing, promoting alternative ideas and viewpoints into the trending topics proves challenging because retweets make up just less than one-third of all trending topics.

Twitter draws criticism for its supposed failing to recognize trends that users perceive as relevant. Some call this failure “censorship” conducted by the company itself. Two trends that drew attention to this issue include “#wikileaks” and “#occupywallstreet.” Three reasons explain these exclusions. One, the algorithm focuses more on novelty than simple frequency. Two, users might misperceive the actual popularity and pace of a trend. Three, the trend might have previously appeared under different terms or locations. Still, the site ensures that no profanity, violence threats, and copyright violations appear within these trending topics, thus raising questions about the possibility of censorship.

Trendrr

Founded in 2004, Trendrr.tv (formerly Trendrr.com) is a subscription-based analytics service specializing in graphical representations of social media traffic relating to television networks, programs, and advertisements, both historically and in real time. Trendrr combs social networking sites (primarily Twitter, Facebook, and the social TV viewing app GetGlue, and others) for mentions of programs, brands, and characters, and compiles data to gauge the social influence of each topic. The Trendrr dashboard, which graphically presents the “influence level” of a television phenomenon, is marketed to television networks, potential advertisers, cable television or multiple-system operators (MSOs), news agencies, and political organizations and candidates.

Many of these entities have found Trendrr useful for measuring online chatter about their programs and products, and note that these quantitative representations can supplement traditional television ratings data and result in actionable programming or advertising decisions. Further, Trendrr data are often cited in news reports by major print, television, and Web agencies. Trendrr has also supplanted more qualitative methods of following audience trends within social media, and is unique among its data-oriented trend spotting counterparts (like the Google-owned Trends and Insights) in that its data gathering is not limited to a single online platform.

Trendrr is owned and operated by digital marketing agency Wiredset, which was founded in 2004 by Mark Ghuneim and Tom Donohue, both former employees of Sony. Ghuneim and Donohue launched the first version of Trendrr in 2006 under the name Infofilter (the name was changed to Trendrr in 2007). In October 2012, after six years of review, Trendrr’s proprietary “system and method for processing data” was awarded a U.S. patent. Though it launched as a free service, within nine months, owners moved Trendrr to a pay model in order to capitalize on increased interest in quantitative analytics within the media industries. According to business blog Fast Company, access to the Trendrr service costs a monthly rate of between \$499 to over \$2,499 for its “enterprise package.”

For the monthly fee, subscribers gain access to “dashboards” that collect data for a given

number of trends (the fee increases as more trends are monitored). A dashboard includes an aggregate number of daily or weekly mentions (“total volume”) of a given program, network, or brand, along with charts of volume ranked by social network (with Twitter, Facebook, GetGlue, and Miso sourcing most of the data).

The dashboard also monitors historical trends from week to week, and breaks down daily social media mentions according to pre-air, during air, and postair time periods. Trendrr also offers dashboards that focus on data specific to Twitter, Facebook, and GetGlue, marking percentage changes from week to week, and representing mentions by time of day in a line graph. Additionally, clients can view a live timeline feed of all social media mentions as they happen, and can map trends for popularity of individual characters on a television program. The Trendrr interface uses natural language analysis to gauge positive, negative, and value-neutral mentions of products, programs, and characters.

News and Politics

While Trendrr has marketed itself heavily toward analysis of social media discussions of prime-time television programs (with ramifications for potential advertisers), the service produced some notable information in regard to the 2012 American presidential election. Trendrr aggregated social networking data relating to many of the year’s major political events, including the Republican and Democratic conventions, the three presidential debates, and media coverage during Election Day. As picked up by several online and offline media organizations, Trendrr data suggested that CNN “won” the election cycle on social media, gaining more online mentions during the debates, conventions, and vote counting than its closest competitors FOX, NBC, MSNBC, and ABC. Trendrr also noted that during televised election-related events, men were more likely to be socially active online than women were (a reversal of the common trend during other kinds of prime-time programming), and that networks that used hashtags to promote their political content on social media tended to have greater social media performance than those that did not. Trendrr attests to its usefulness in news and politics by marketing itself as an accurate measurer of

popularity of news topics, news personalities, and political candidates.

Conclusion

Trendrr's founders have attempted to position the platform as a useful and necessary outgrowth of a broader trend of "social TV," wherein consumers of television increasingly use personal computers and mobile devices as additional methods of engagement with televised content, from news and political events to sports, entertainment awards shows, and daily viewing. As television content continues to outgrow the constraints of its original medium, quantitative trend aggregators like Trendrr may become more useful to networks, advertisers, political groups, and media owners.

created to combat rumors, misinformation, and false or misleading claims about Obama and his campaign. In addition to defending the president and his record, the Truth Team highlighted what they believed to be inaccurate or misleading statements made by Mitt Romney's campaign. Using the slogan "Know the Facts. Get the Truth," the campaign encouraged voters to join the team to receive factual corrections to claims made about Obama, or more general misrepresentations made by the Romney campaign, although at least one mainstream media site, ABC News Online, suggested that the team sometimes confused "criticism" with "smears." The campaign's goal to correct inaccurate information was similar to Obama's 2008 "Fight the Smears" campaign. The Truth Team campaign addressed several prominent misperceptions, for example, claims that Obama was not born in the United States, that his administration purposely leaked national security information for political gain, and inaccurate beliefs about the Affordable Care Act. The Truth Team also highlighted misinformation regarding Obama and Romney's policy goals.

The Truth Team campaign heavily relied on social media platforms to provide people corrective information. Visitors to the Team's Web site were encouraged to follow the campaign on Facebook and Twitter, which provided updates directly to users' social media platforms. In addition, corrective articles on the site included tags that allowed visitors to instantly share the information on Facebook and Twitter, or e-mail it to other people.

The Truth Team Web site was divided into several distinct subsections. First, the "Attack Watch" segment highlighted misleading claims aimed at President Obama that surfaced in the news, online, or in political advertisements. The Web site provided evidence challenging inaccurate claims, and often directed visitors to external news sources or fact-checking Web sites such as Factcheck.org or Politifact. The second section, labeled "Romney's Distortions," reported on what the Truth Team felt were false claims made by the Romney campaign. Items in this section were often focused on differences between policy statements made by Romney, and his record as governor of Massachusetts. These items were sometimes accompanied by a "Romney versus Reality" tag. The third

Truth Team

Early in President Barack Obama's 2012 re-election effort, his campaign announced the creation of the "Truth Team." The Truth Team was

Among the topics the Truth Team addresses are misconceptions about President Obama's Affordable Care Act. This Tea Party rally against health care reform gathered on March 13, 2010, in St. Paul, Minnesota, to hear Michele Bachmann speak.

section was titled “Obama’s Promises Kept,” and focused on Obama’s political record during his first term in office, including his work with the American auto industry and the Affordable Care Act. This section also highlighted the president’s policy stance on a variety of key campaign issues, Obama’s plan to reduce the federal deficit, or to create jobs.

The Truth Team used multiple message formats in an attempt to reach voters. Many of the items produced by the campaign took the form of written rebuttals to inaccurate information. These items generally offered the misleading claim, followed by a series of facts or evidence intended to dispel them. In addition, the campaign used a series of videos and graphical information to persuade users of the site. The videos employed a variety of themes; some videos featured direct appeals from Obama or other prominent politicians like former President Bill Clinton. Other videos featured citizens discussing why they were supporting Obama, or included a series of clips from news organizations that attempted to rebut the false information. The infographics used by the Truth Team often featured simple graphs highlighting differences between the Obama and Romney campaigns on

a variety of issues including the economy, job creation, and taxes.

The final section of the Truth Team Web site allowed citizens to report perceived falsehoods that they encountered during the campaign. This “Fight Back: Report an Attack” section asked citizens to contact the Truth Team with information about misleading claims, including when and where the claim was encountered.

Impact

Despite the efforts of the Obama Truth Team to correct false information, national surveys suggest that many Americans maintained misperceptions about the president. For example, according to a July 2012 survey conducted by the Pew Research Center, 17 percent of voters believed that Obama was Muslim, including 30 percent of Republicans. The extent to which these false beliefs impacted voting behavior is yet to be determined, especially given that President Obama’s re-election campaign was successful. However, the percentage of voters who remained misinformed even with an aggressive truth campaign highlights the power of rumors and misperceptions and the difficulty that presidential campaigns face in overcoming them.

Truthout

Truthout is a 501(c)3 nonprofit "online-only" news organization that publishes investigative reporting, critical analysis, and op-ed commentary. Since its founding in 2001, the site has established itself as an influential and sometimes controversial source in progressive independent media by publishing featured content from well-known journalists and opinion writers and extensive coverage of political, economic, and social issues. Truthout's strategic use of a variety of social media platforms has also been an important factor in its visibility, fundraising, and in the maintenance and growth of its audiences. The site currently serves over a million unique visitors per month through its network of Web sites and its daily newsletter.

While the domain truthout.org was officially registered in 2001, several sources point to the aftermath of the 2000 presidential election as the context of the site's beginnings. Photographer Marc Ash and other media activists were inspired to start the site in response to what they felt was an insufficient mainstream media response to the U.S. Supreme Court appointment of 43rd U.S. President George W. Bush after the contested election. Truthout was founded as an alternative to existing media outlets, including trusted sources such as the *New York Times* and NPR.

Truthout commissions articles from in-house and outside journalists and secures permission to reprint select articles. Their reporting includes coverage on a wide range of domestic and global political issues including election politics, the Iraq War, interrogation techniques, health care, the economy and wealth inequality, veterans'

health issues, the labor movement, environmental issues, prison reform, and the FBI's monitoring of Occupy Wall Street protests. In many cases, original Truthout content has been picked up by mainstream media sources and cited in legal proceedings related to these events. The organization holds a contract with the nationwide Newspaper Guild/CWA, and claims to be the first online-only news site to successfully unionize. They facilitated that process online through virtual meetings and member authorization.

Social Media Reach and Collaborations

Truthout's primary social media platforms are Facebook and Twitter, with Facebook the largest single source for referrals. In fiscal year 2011, Facebook traffic accounted for 38 percent of readers who visited truthout.org via another site (including cellphone and mobile device users). As of December 7, 2012, Truthout's Facebook page showed 171,480 "likes" and their Twitter account had 56,195 followers. Buzzflash, Truthout's closely affiliated sister site, had 4,139 "likes" on its Facebook page, and 29,419 Twitter followers. Truthout also has a presence on sites such as Reddit and Google+. The site has a YouTube channel, and has experimented with Pinterest and Tumblr, but these are less of a focus of its social media strategy. Truthout also targets and shares its audiences by linking to coproduced and/or licensed radio and video content with partners such as Bill Moyers, Thom Hartmann, Richard Wolff, the ACLU, and various independent media outlets.

Coverage and Controversies

Truthout has produced significant coverage of U.S. torture policy in the War on Terror. A 2009 report on the Bush administration's authorization of controversial interrogation techniques was cited by MSNBC's *Countdown with Keith Olbermann*, and eventually by Senate Armed Services Committee Chairman Carl Levin. Truthout's Jason Leopold wrote the initial piece discussing the Department of Justice's retraction of its earlier claims that waterboarded detainee Abu Zubaydah was the third-most powerful official in the Al Qaeda organization, and that he helped to plan the September 11, 2001, terrorist attacks.

Truthout's highest-profile controversy occurred when reporter Jason Leopold wrote that U.S.

Attorney Patrick J. Fitzgerald had handed an indictment to Karl Rove for his role in the leak that disclosed the identity of C.I.A. agent Valerie Plame. Rove and his attorney flatly denied this claim, which prompted widespread speculation and commentary in both traditional and alternative news media about Truthout's journalistic standards. However, both Leopold and Truthout Director Marc Ash stood by Leopold's source until Fitzgerald's June 13, 2006, announcement that he would not indict Rove. Truthout then offered an official apology to its readers saying that on this matter, it deferred to the nation's leading publications.

Truthout published coverage of safety issues at various British Petroleum (BP) operations following the April 2010 explosion at the Deepwater Horizon oil drilling platform in the Gulf of Mexico. These reports, which included first-hand testimony and other evidence of future oil spill risks, were cited by several mainstream media outlets, including *60 Minutes*, the *Los Angeles Times*, and CNN. They were also cited by the U.S. House of Representatives Committee on Transportation and Infrastructure during a hearing on the safety of hazardous liquid pipelines.

Truthout claims to be the first news organization to ever file a Freedom of Information Act request with the Department of Homeland Security. This request was filed in connection to Truthout's investigation of the agency's extensive monitoring and shutdown of various Occupy Wall Street protests.

Truthy Research Project

Truthy is a research project intended to analyze Twitter in order to separate the true from the merely "truthy," or seemingly true but actually false, in tweets on political topics. The word *truthy* was coined by comedian Stephen Colbert, and means misinformation masquerading as fact. The project analyzes patterns that online political discussions create, and makes all of its findings publicly available, with the ultimate goal of making everyday users more aware of the manipulation of data.

According to its lead researcher in 2010, Filippo Menczer, the ultimate research question asked by Truthy is "Can we put together our understanding of complex social networks and crowdsourcing to automatically detect the spread of misinformation?" The goal of Truthy is comprehension of the ways that information is created and recreated via complicated informational relationships, which are social and technical. The hope is that utilizing tweets as sociocultural and "behavioral trace data" researchers will be able to understand and predict the way that information spreads at a unique level of fine detail.

Truthy researchers are attempting to study the ways that information profligates via social media networks and other online relationships. Truthy uses the Twitter database of memes and usernames in order to assess the frequency at which a meme is mentioned. It gathers samples of tweets from Twitter using the Web site's "Streaming API." This designated sample is alleged by Twitter to be random and representative. This sample only

covers three months back, but because Truthy began gathering the data in September 2010, it has a broader sample.

The system also performs basic sentiment analysis by comparing Twitter memes and tweets against psychologically designed databases of words. In this way, it discerns a meme or tweet's mood or emotion; it will see that someone has mentioned #Truthy, and then assess based on the words and word patterns around the meme how the user feels about it.

Researchers ask that visitors to Truthy flag memes that appear to be manipulated as "truthy." This crowdsourcing aspect of the project is hoped to be a large part of revealing the patterns of misinformation and ultimately aid researchers in covering more ground faster vis-à-vis development of algorithms for automatic identification of Twitter abuse. Researchers are aware that crowdsourcing may or may not be reliable; this is part of the long-term research plan.

The Truthy Project created a unique way to graphically image memes as they evolve. These meme maps depict the ways that users interact with color coding; they trace tweets, retweets, and @replies. As each new topic develops, the cluster of user interactions about that topic visually grows. In the case of political topics, the meme map tends to show two distinct clusters around a general topic. For example, if the topic were #BarackObama, there would likely be two clusters, one conservative and one liberal. Members in each group tend to talk to and about each other using like phrases and echoing each other. All of these trends create distinctive looking meme maps.

The Truthy Project was inspired by a study from early 2010 by a professor of computer science at Wellesley, Pagiotis Takis Metaxas. Metaxas studied Twitter "bombs" used by a conservative political group on an election day. The bombs were cascades of messages intended to manipulate trending on Twitter and, ultimately, Google results as they reported results in real time.

Truthy uses as its basis a sentiment analysis system designed to predict market trends and instead adapts it to assess political sentiment. Truthy researchers have begun this process by generating analyses of political affiliations, partisan speech in online political participation,

and communication within and across various ideologies.

By 2012 Truthy researchers were working to expand the Truthy platform and make its data more accessible to professional, technical, and lay-public users. They were studying how and why certain memes go viral and the ways that sentiment plays into the spread of information, such as what factors influence popularity in the political setting. Researchers were also working toward automation of the Truthy process. Finally, the ultimate goal in 2012 was to detect astroturfing, political smear campaigns, and other social manipulation.

In March 2012, Harvard University and MIT jointly sponsored a Truthiness in Digital Media symposium that "[sought] to understand and address propaganda and misinformation in the new media ecosystem." The symposium featured data, presenters and papers from the Truthy Project.

In 2012, the principal investigators behind Truthy were Fil Menczer, Alessandro Flammini, Johan Bollen, and Alessandro Vespignani. Other members of the research and Web development team included Michael Conover, Karissa McKelvey, Clayton Davis, Alex Rudnick, Jacob Ratkiewicz, Bruno Gonçalves, Mark Meiss, Snehal Patil, Luca Aiello, and Przemyslaw Grabowicz.

Tumblr

Tumblr draws upon a history of other blogging sites such as LiveJournal, Wordpress, and Blogger, but what sets it apart is its alignment with the trend of microblogging sites such as Twitter. Tumblr makes it easy to post content because it provides single-click options for the posting of a picture, video, audio, Web link, or text. Just as political bumper stickers were once a clear way of sharing opinions and making a message enter the public consciousness, Tumblr contributes to the sharing and replicating of images and memes to the point where they reach viral levels of transmission. By 2012, political campaigns, news media, and advocacy groups had all incorporated Tumblr into their social media and Web strategies.

Like other forms of social media, the ability to easily follow content feeds, discover new content through links, and search for new content via tags provides Tumblr users a convenient way to aggregate news stories from content sources. One of the key features is the ability to simply reblog another post. Like other blogging and social media platforms, users can import a social graph or easily add new Tumblr blogs to their feed by subscribing to a particular blog.

This feature works like following on Twitter, adding on Facebook, or adding an really simple syndication (RSS) feed to a reader/aggregator. One easy way that users do this is via hashtags such as #politics, #Iran, or #TeaParty. Users can post content and have it align with a particular

hashtag to make it more easily searchable to others, and vice-versa, users can search hashtags to find all content relating to a particular topic.

A common use of Tumblr is for creating a simple “single-serving site,” which generates a particular type of content such as a particular image with variations in the text. One of the most famous examples of this was the “Texts From Hillary Clinton” Tumblr, which used a photograph of Hillary Clinton (taken by Diana Walker for *Time* magazine) wearing sunglasses and texting on her phone.

The photo is often combined with another photo of someone ostensibly texting Hillary, with Hillary offering a flippant or pithy answer. This site became so popular that Hillary Clinton responded to the creators via text message, and President Barack Obama mentioned the phenomenon in his 2012 White House correspondents’ dinner speech. Similarly, the “Hey Girl, It’s Paul Ryan” Tumblr riffs on the famous Ryan Gosling meme of a similar name, and produces pictures that highlight Paul Ryan’s attractive looks with text overlay that focuses on matters of public policy.

Of course, for politicians, the use of Tumblr allows their campaigns to tap into existing user communities and provide those communities with very easy ways of duplicating and disseminating messages, images, and video provided by the campaign’s official Tumblr blog. In the 2012 presidential election, Mitt Romney and Barack Obama’s campaigns were highly active on Tumblr just as they were on Facebook or Twitter. Importantly, the content distributed via these networks was not always duplicated because each site provides a different way to engage with the voting public.

Like many other blogging platforms and social networking sites, Tumblr has gained a sizeable user base, and has integrated itself into the everyday online practices of many people. While it is a platform for many different uses, its ability to simply create and share content with a wide audience has turned it into an important tool for politicians, activists, and individuals interested in gathering news and information.

TuniLeaks.org

TuniLeaks is a set of diplomatic cables made public by whistleblowing Web site WikiLeaks that illuminated neglect of human rights in Tunisia, freedom of expression restrictions, and widespread corruption of the former Tunisian ruling party. TuniLeaks is the name of the Web space provided by Nawaat.org, an independent collective blog on Tunisia that first published the documents several weeks before widespread citizen uprisings in December 2010 and January 2011, which resulted in President Zine el-Abedine Ben Ali and family fleeing the north African nation on January 14, 2011. Nawaat.org launched TuniLeaks on November 28, 2010, only one hour after WikiLeaks released the documents. The hashtag #tunileaks was created on Twitter so that people within and outside the nation could share various details revealed by the leaked documents. In addition, the Al-Jazeera network played a significant role in translating the cables into other dialects of Arabic and informing broader publics about the content of the leaked diplomatic documents.

The Tunisian government rapidly halted access to TuniLeaks by blocking <http://tunileaks>

.appspot.com within Tunisia. On November 29, the government blocked Google App Engine's Internet protocol (IP) address so that TuniLeaks access under https would also be blocked. The government had previously blocked nearly all Web sites on domestic human rights and political opposition, and was in process of obtaining all Tunisian Facebook users' sites via a state-sponsored phishing attack. Access to other international media that reported on the leaked cables, such as Lebanese news organization Al Akhbar, was also blocked. Hacktivist collective Anonymous responded with a distributed denial of service (DDoS) attack to take down the Tunisian government's Web site in an effort known as #optunisia.

TuniLeaks solidified what Tunisian citizens had known for years, but were unable to publicly articulate. Tunileaks reported the following:

The problem is clear: Tunisia has been ruled by the same president for 22 years. He has no successor. . . . His regime has lost touch with the Tunisian people. They tolerate no advice or criticism, whether domestic or international. Increasingly, they rely on the police for control and focus on preserving power. And, corruption in the inner circle is growing. Even average Tunisians are now keenly aware of it, and the chorus of complaints is rising. . . . Anger is growing at Tunisia's high unemployment and regional inequities. As a consequence, the risks to the regime's long-term stability are increasing.

While Tunisian citizens had a keen sense of the extensive extravagance and corruption of the Ben Ali regime, and in particular the Trebelsis, the extended family of First Lady Leila Ben Ali during his 23-year reign, the leaked documents added clarity and a corpus of specific detail, strengthening consciousness of the privilege of the power elite to which citizens had previously been unaware.

From large-scale power architecture, such as the need for certain connections to do anything from starting a small business to engaging in seizing of property, to insidious excessive luxuries such as a pet tiger that was fed four chickens each day (more than some Tunisian families might

A young woman in an Anonymous t-shirt looks out over a May 1, 2012, protest in Tunis, Tunisia. The Anonymous collective launched a distributed denial of service attack on the Tunisian government's Web site in response to Internet censorship in 2010.

consume in a week), Tunileaks solidified the deep sense of inequity experienced by Tunisian citizens. It underscored numerous struggles: a high unemployment rate (20 percent of the population who are of working age, or 750,000 people); the futility of professional development and meritocracy (25 percent of that population of unemployed are college graduates); and an unwieldy bureaucracy of rules, regulations, and laws to which the elite are immune.

For example, one document reported on a yacht, allegedly stolen from a French businessman by Ben Ali's nephews, Imed and Moaz Trabelsi. Tunileaks reported,

The numerous stories of familial corruption are certainly galling to many Tunisians, but beyond the rumors of money-grabbing is a frustration that the well-connected can live outside the law. One Tunisian lamented that Tunisia was no longer a police state, it had become a state run by the mafia. "Even the police report to the Family!" he exclaimed.

Perhaps the elite's living "outside the law" was particularly galling to Tunisian citizens after they learned of the self-immolation of Mohamed Bouazizi on December 17, 2010. Bouazizi, a fruit and vegetable vendor in the provincial town of Sidi Bouzid, had been repeatedly hassled by local police officers, who confiscated his scales

and the produce he attempted to sell from his humble market cart because he lacked what they claimed was a necessary permit and funds to pay a recent city fine of 400 dinars (\$280, equivalent to two months of his wages). Normally, a *bakshish* (bribe) would be enough to keep the officers at bay, but on this particular day, a local police-woman slapped Bouazizi's face and cursed his late father, an act of public humiliation and demoralization that led Bouazizi to douse himself with kerosene and light himself on fire in front of the municipal office that refused to hear his concerns.

Given the timing of the release of the documents, which gave evidence to the vast divide of the elite and the disempowered, TuniLeaks, Bouazizi's self-immolation, and the following protests in Sidi Bouzid fueled public protests elsewhere. These have since been named the Jasmine Revolution, and the first of numerous uprisings in Egypt, Bahrain, Yemen, and elsewhere in the Middle East and north Africa that are now known as the Arab Spring.

Tunisia

On December 17, 2010, a young fruit vendor named Mohamed Bouazizi self-immolated in the Tunisian city of Sidi Bouzid after experiencing harassment from police. Bouazizi's act sparked

protests in the city, which were captured on cellphone and other cameras and uploaded to social media sites, causing the demonstrations to grow and spread throughout Tunisia. With international media largely prevented from entering the country, journalists used social media to identify sources, locate images, and report on the growing unrest, while bloggers and activists produced images and videos that they shared with the world on sites such as Facebook. In response, the Tunisian government, which had for years conducted censorship and surveillance on online networks, responded with sophisticated cyberattacks. The protests, which lasted for nearly a month, eventually led to President Zine El Abidine Ben Ali fleeing with his family to Saudi Arabia, ushering in a new era of governance for Tunisia.

Official state media did not report on the protests initially, and with international media largely absent from the country, the growing unrest at first went unreported. By December 28, a select few international media outlets had begun to report on the demonstrations. Using images taken by Tunisian blogger and 2011 Nobel Peace Prize nominee Lina Ben Mhenni, Al Jazeera English became one of the first major English-language outlets to report on the demonstrations, calling them a “rare display” of popular anger. Another media outlet to report on the demonstrations early on was France24, which, using amateur footage sourced from social media, issued its first report on December 27. Some bloggers, including Mhenni, traveled from one city to another to capture such footage.

Spreading Information

Meanwhile, Tunisian blogs and independent news sites had been reporting on the unrest since it began. The award-winning Tunisian site Nawaat.org, which was founded by Tunisian exiles in 2004 and had risen to prominence for its various campaigns—such as one in which it mapped unofficial use of Ben Ali’s presidential plane—began aggregating videos, images, and other updates from the ground on its site as early as December 17.

On Twitter, Tunisians used the hashtag #Sidi-Bouazid to share information about the demonstrations, while existing networks on Facebook and other sites were used to aggregate

information about upcoming protests, as well as videos and images of ongoing ones.

Videos proved to be particularly powerful, offering Tunisians in disparate locations a view into what was happening in other cities. From Kasserine, where the government’s crackdown was particularly harsh, emerged videos showing that police officers were using live ammunition against protesters.

At times, social media also proved ripe for rumors: On January 12, a Tunisian Twitter user reported the possibility of a coup, which quickly spread across Twitter, and was eventually as reported on by technology site The Next Web.

Circumventing Censorship

Although Tunisia’s Internet penetration was relatively high at an estimated 36 percent (thanks in part to government efforts to expand usage), its Internet was pervasively censored, causing the country to frequently be named one of the most censorious in the world by groups like Freedom House and Reporters Without Borders. Among the Web sites blocked were those critical of the country’s human rights record (such as hrw.org and rsf.org); local opposition sites and blogs; anonymizer and proxy tools; and popular video-sharing sites such as YouTube, Vimeo, and DailyMotion.

Social media had nevertheless become popularized in the years prior, with some sources claiming that the number of Tunisian Facebook users exceeded 1 million in 2010, giving it one of the highest rates of Facebook use per capita in the world. Two factors contributed to the popularity of Facebook: In 2009, mobile phone operator Tunisiana introduced low rates that enabled Tunisians to access Facebook from their mobile phones, and the blocking of other popular platforms (particularly those that allowed video-sharing) led to Facebook emerging as a central, accessible platform for sharing photos, video, and written content.

Although most video-sharing sites were blocked, diaspora and solidarity networks outside the country posted videos to YouTube in an effort to gain more attention for the demonstrations. Nawaat.org maintained a dedicated YouTube channel for videos coming out of Tunisia throughout the period of unrest.

In addition to censoring the Internet, the Tunisian government had been monitoring online activity using sophisticated methods such as deep packet inspection (DPI), and had harassed and jailed bloggers starting as early as 2001. Tunisian Internet service providers (ISPs) were required to lease bandwidth from a central agency, the Agence Tunisienne d'Internet (ATI)—the governing body set up by the Ministry of Communication in 1996—giving that agency the capability to install filtering and surveillance software to monitor all of the country's networks. In addition to technical surveillance, the ATI held Internet café owners and state-controlled public Internet centers (or “publinets”) responsible for their customers' activities, and required them to register the IDs of Internet users.

The extent of control exerted over the Internet by the ATI was widely known to activists, who had dubbed the censorship regime “Ammar404,” a personification that played on the 404 error message served up by censors in an effort to disguise their censorship. Over the years, numerous campaigns, both serious and humorous, were leveled against Ammar404 online.

Aware of the utility of social media in fomenting further unrest, the government began to seek out new techniques for intimidating users. Without a system in place, authorities resorted to a piecemeal approach, which included conducting man-in-the-middle attacks that redirected Facebook users to a fake login page, resulting in Tunisians attempting to access Facebook accidentally handing their login information, including their password, to Tunisian who were authorities. Victims of these attacks would later log into Facebook and find that their accounts had been hijacked or deleted. Some Tunisian social media users complained of government infiltration of Facebook groups, a possible result of account hijackings.

The attacks were combined with an increase in online censorship, as well as the targeted arrests of bloggers, journalists, and online activists. Prominent blogger Slim Amamou was detained at the Ministry of the Interior, which he reported to his online friends and followers using Google Latitudes. Lina Ben Mhenni and another well-known blogger, Sofiane Chourabi, found their e-mail and Facebook accounts hacked.

In response to the attacks, sympathetic foreign groups such as the collective known as Anonymous defaced and attacked government Web sites under the banner of “TunisOps.” The collective managed to successfully disable the Web site of the country's prime minister and the homepage of the Tunisian government. They also sought to provide information that would help Tunisian Internet users access online security, censorship circumvention, and anonymity tools.

In what would be Ben Ali's final speech addressing the Tunisian people, he promised an end to censorship in the country and an end to his rule by 2014. The speech was heavily tweeted by Tunisians, still using the #SidiBouazid hashtag. Three hours after Ben Ali's speech, Slim Amamou tweeted “Je suis libre” (“I am free”), signaling his release from the Ministry of Interior. The next day, Tunisians reported the Web site blocks to have been lifted, and media reports confirmed that Ben Ali had fled with his family to Saudi Arabia.

WikiLeaks

Whistleblowing organization WikiLeaks' release of diplomatic cables occurred just weeks before the first signs of protest. Nawaat.org, the popular Tunisian news site, had made a deal with WikiLeaks that allowed them to translate and release a set of cables related to Tunisia simultaneously with the *New York Times* and other major media on November 28.

The site hosting the cables, tunileaks.appspot.com, was rapidly blocked by authorities, which—realizing that Tunisians were able to route around the censorship by going to the encrypted version of the site at <https://tunileaks.appspot.com>—blocked Google App Engine's IP address, resulting in a partial block of the Google product's site. Later, when Lebanese news site Al Akhbar republished some of the TuniLeaks cables, authorities, blocked that Web site also.

While some, including Amnesty International and WikiLeaks founder Julian Assange, credited the 2010 cable release with prompting the uprising, others viewed the whistleblowing site as having a limited role. Sami Ben Gharbia, one of the cofounders of Nawaat.org, argued that because the cables were then available for Tunisians to read, they helped tip the balance by confirming

what many citizens already knew. Prominent award-winning Egyptian blogger Wael Abbas shared Gharbia's sentiment, comparing the role of WikiLeaks to that of the many videos he had posted of Egyptian police brutality.

Social Media

The international attention afforded Tunisia, and the resulting support of the people's demands by foreign governments, including the United States, may have in the end forced Ben Ali's hand. That international attention took weeks to attract, and was drawn by social media, indicates that the documentation and reportage of protests on social media by participants and amateur observers was significant. Once the world's attention

was drawn to Tunisia, foreign media, particularly broadcast media, continued to rely on content gleaned from social media in its reporting. Al Jazeera called on individuals to submit their amateur footage to the station for rebroadcast, and continued to utilize citizen media throughout the Arab Spring. The station's viewership was far bigger than the number of citizens that Facebook could reach.

Whether social media played a role in the communications infrastructure of the protest movement remains a debated topic. Research from the Dubai School of Government shows that a majority of Tunisians (88.1 percent) report that the majority of news they accessed during the protest period came from Twitter and Facebook,

Protesters holding a sit-in in the Kasbah area of Tunis on January 28, 2011. Despite the country's extensive pattern of Internet censorship, Tunisians accessed Facebook and Twitter during the revolution, when as many as 88 percent of all Tunisians got most of their news from these sites. Some claim that there were more than 1 million Facebook users in the country in 2010, which, even before that number more than doubled after the revolution, would make it one of the highest rates of Facebook use per capita in the world.

indicating that the sites may have played a role in spreading the protests. Additionally, a sharp increase in the number of Facebook users between 2010 and 2011 (from an estimated 1.1 to 2.3 million) may indicate that Tunisians joining the site did so because of its utility in the Arab Spring protests.

The role of mobile networks, including the use of SMS as an organizing tool, is also important: In 2009, an estimated 95 percent of Tunisians had a mobile phone subscription, and many of those phones had cameras that were used to record images and video of protests. SMS was also reportedly an important tool for sharing location information of protests.

Tunisians and scholars have pointed out that online activist networks in the country had been building for at least a decade. Early blogs, such as TUNeZINE (whose founder, Zouhair Yahyaoui, was imprisoned for his blogging and later died, reportedly of injuries caused by torture during his imprisonment) broached political topics that were considered off-limits, contributing to the country's culture of political blogging. Nawaat.org's popular campaigns also contributed toward the politicization of young Tunisians.

In 2008, protests in the region of Gafsa prompted the ATI to ramp up its censorship, as activists were using Facebook to spread information about the events. The ban on Facebook sparked protests, leading the government to lift the ban after about two weeks. The ban, and the success of protests in overturning it, also emboldened free speech activists, many of whom would go on to play significant roles in the uprising.

The country's tight restrictions on media had allowed a blogging and citizen journalism community to flourish, and Tunisian digital activists had been operating innovative campaigns since the early 2000s. According to an interview with Nawaat.org's Gharbia, many Tunisian activists were integrated into networks that spanned the Arab region. Many prominent bloggers were also among the first to participate in the street protests. Howard and Hussain muse that Bouazizi's death merely pushed those virtual networks into physical public spaces.

Still others have framed social media's role as an oppositional information/action cascade: Enough Tunisians were in favor of, and prepared

for dissent but only took advantage when it became clear, through social media, that their views were shared by many others. For those who were perhaps not prepared, the videos and images depicting the government's brutal crackdown on demonstrations in cities like Sidi Bouzid and Kasserine that spread rapidly across social networks may have been a tipping point.

Tweet Insurance

With social media becoming increasingly prominent, odds are that all individuals participating have made a comment or statement on a platform that they regret. While for an individual, the effects of a single misguided retort is likely minimal, for large companies or politicians the results can be damning. As a result, the Kiln Group—an underwriting firm at Lloyds of London—has begun working to protect companies from the damages sustained from insensitive postings on social media Web sites, especially Twitter. As employers continue to increase their use of sites such as Facebook and Twitter to market products, communicate with customers, and collect information, they leave themselves open to regulatory, legal, and reputational risks. With the use of social media in the corporate world comes the potential for problems with privacy issues, intellectual property infringement, and defamation. For \$100,000, a company can receive \$10 million in coverage to protect its brand identity from damage caused by poor choice of words.

The concerns revolve around the fact that Twitter is a clear mode of communication. If false statements are made and reputations are harmed, the individual making the comments would face accusations of libel. Companies, understandably, want to be protected from such an occurrence. Lawyers routinely point to the common type of rant in which individuals complain about their employer. Such complaints can lead to lawsuits, and wherever lawsuits are in play, so is insurance. From a political standpoint, the real benefit is still a few years away, according to Kiln. Individuals are not yet eligible to be covered by the insurance program. To provide an example of the difference, one can look at the recent controversy involving actor Gilbert Gottfried. Gottfried was fired as the voice of the Aflac duck because of tweets he sent about the earthquake in Japan. While Aflac would be able to cover itself under the Kiln Group's insurance, Gottfried would be unable to do the same for his personal brand.

Most companies are making the liability possible by not establishing clear written policies for social networking. With policies not in place, incidents with liabilities attached are far more likely to occur. There are countless examples of

poor decisions made on social media sites requiring later apologies to attempt to prevent financial and reputational harm. Consider designer Kenneth Cole and his tweet about the civil uproar in Cairo actually being about the release of the designer's spring collection online. Singer Courtney Love faced financial repercussions (upward of \$500,000) for posting negative, disparaging comments about a fashion designer in 2009. These are only two of numerous cases in which tweet insurance could be useful.

It should be noted, however, that most insurance analysts do not believe that their companies will be willing to provide coverage to everyone who asks for it. Brokers will likely be far more selective in deciding who is eligible for tweet insurance. Brokers will want to see clear evidence of self-control. Including attorneys, self-monitoring preposting, and examination of all pending posts will lead to better odds of being covered (along with lower premium amounts).

For the political world, tweet insurance is a distant possibility. For now, only corporations are eligible, and even they are under close scrutiny when applying. The difficulties in insuring politicians include how to assess value for things like lost voters or decreases in donations. Likewise, how will media coverage be assessed? These are just a few of the many questions that will need to be considered and answered before political figures can look toward Lloyds of London for help in recouping losses from accidental keystrokes and mistimed tweets broadcast for the world to see.

Twestival

Largely attributed to the ongoing efforts of lead founder Amanda Rose, Twestival is a grassroots movement that entails the uniting and mobilization of otherwise dispersed global and local communities via Twitter. Additionally referred to as Twitter Festival, Twestival refers to tweeters' strategic use of the microblogging platform Twitter to organize festive, recurring, offline, one-day social fundraising gatherings on short timelines. Twestival's infrastructure provides a virtual rendering of traditional grassroots movement procedures by crowdsourcing tweeters, tech-savvy practitioners, and sponsors for the purpose of running a virtual online campaign with a two-fold objective of transforming virtual tweeter relationships into real-world social gatherings, and using the gathering to raise awareness about and donations for a specified social cause. The active reinterpretation of traditional offline grassroots communication tactics, paired with a short timeline, enables Twestival to successfully facilitate recurring opportunities to "collaborate on a global scale from the local level." Twestival's success to date demonstrates how grassroots movements have evolved to be effective in time-conscious, virtual-relationship-driven contexts.

Twestival, originally a one-day event called Harvest Twestival, was founded in late summer 2008 by Amanda Rose, Ben Matthews, Tim Hoang, and Tom Malcolm, a group of friends interested in using the microblogging site Twitter to bring together PR practitioners for a night of fun. Organized in under two weeks and attended by 250 people, Harvest Festival operated as an event solely funded by donations of time, money, technology, and technological expertise.

The 2008 Harvest Twestival's innovative social-media-driven infrastructure was comprised of two central complimentary objectives. As a primary objective, Harvest Twestival enabled Twitter

users to meet face-to-face in a fun social setting, transforming virtual relationships and interactions into real-world ones. As an auxiliary objective, Twestival provided an event that facilitated the collection of both monetary and food donations for the nonprofit organization The Connection. The success of the Harvest Festival event, held on September 25, 2008, demonstrated the ability to effectively leverage a social media platform to facilitate a fundraising event in support of a nonprofit organization while encouraging festive social interaction. As such, Harvest Twestival served as a model and evolved into Twestival Global and Twestival Local.

Twestival Global

Twestival Global was established on January 8, 2009. Using the Harvest Twestival model, Twestival Global expanded to include 202 cities around the world, mobilizing over 1,000 volunteers through Twitter crowdsourcing. The recipient of Twestival Global's efforts was the nonprofit organization charity Water.org, an organization located in New York that executes projects to build sustainable clean water sources in developing countries. Twestival Global culminated in a series of one-day events around the globe that took place on February 12, 2009. In all, 202 cities participated, raising in excess of \$250,000. In line with Twestival's mission, 100 percent of the proceeds were used to create 55 sustainable wells in Uganda, Ethiopia, and India, the first of which was built in Ethiopia.

In 2010, the nonprofit organization Concern Worldwide, an organization focused on global education, was the focus of Twestival Global. On March 25, 2010, over 175 cities worldwide participated in Twestival Global and raised over \$400,000 in support. The proceeds were used to fund projects in Malawi, Liberia, Haiti, and Burundi.

Twestival Local

Twestival Local provides opportunities for individuals to fundraise for a nonprofit and cause that impact one's community. During the September 2009 Twestival Local campaign, a total of 133 cities around the globe raised over \$478,000 for 135 nonprofit organizations, such as Discovering Deaf Worlds and Khushboo Welfare Society. During the March 2011 campaign, 150 cities

participated worldwide and raised \$565,000 for select nonprofit organizations.

Twestival Now

In all, over 200 cities and 45 countries have raised \$1.75 million in donations by holding Twestivals for more than 275 causes. Twestival, as of 2012, is on an indefinite hiatus, as per lead founder Amanda Rose's July 2011 final blog post concerning the future of Twestival. Ultimately, Twestival attests to the rapid assimilation of social media for social action purposes.

Twindex

Measuring individuals' intentions to vote in American elections can be traced back to the early days of the Republic. Historically, this task was largely a function of political parties and journalists. However, in the early 1900s, professional polling firms began using scientific methods to predict election outcomes. During the 2012 U.S. presidential election, a new election prediction mechanism joined the fray. The Twitter Political Index, nicknamed the Twindex, provided a daily gauge of Twitter users' opinions about presidential candidates Barack Obama and Mitt Romney. According to Topsy, the index was not conceived to replace traditional polling, rather it was built to "reinforce it" by providing "a more complete picture of the political forecast."

The Twitter Political Index was conceived out of a joint venture between four separate entities: Topsy, Twitter, the Mellman Group, and Northstar Opinion Research. According to its corporate information, Topsy is the "world's only index of the public social Web." Headquartered in San Francisco, the service analyzes the universe of daily tweets in a way that allows users to predict outcomes of events and discover trends. Twitter was officially launched in 2006, with a unique construct of limiting conversation to only 140 characters. Also based in San Francisco, Twitter claims users in "nearly every country in the world," and is available in more than 20 languages. Both the Mellman Group and Northstar Opinion Research are recognized public opinion research firms with strong ties to the American Association of Political Consultants, both U.S. political parties, and candidates for office throughout the country. The index was built using Topsy's analytical platform and Twitter's content. The public opinion research firms helped refine and then validate the methodology used to measure daily changes in Twitter users' sentiment toward the two presidential candidates.

The index sought to rank the positivity of sentiment expressed in tweets on each day of the 2012 presidential campaign, beginning on August 1, 2012, when it was officially launched. Each tweet that mentioned a candidate by last name or specifically mentioned either candidate's official Twitter account was analyzed. Tweets were then compared to the entirety of the day's tweets to determine which candidate received more positive tweets, and how much more positive the nature of the content was than all other tweeted content on that day. Results were then charted on a scale of 0 to 100. On this chart, 50 is considered neutral. Therefore, anything above 50 could be considered positive, and below 50 is negative. Barack Obama was represented with a blue line, and Mitt Romney with a red, following the media's accepted color categorizations of the two major political parties.

In addition to the positive versus negative daily ranking, the index measured tweets about each candidate through the geographic categorization of red, blue, and swing states. Red states were defined as those states the index considered "solid Republican." Blue states were considered "solid

Democratic,” and swing states were considered a toss-up. By using GPS geotagging, the index tracked and charted tweets originating from each state, and ranked the candidates using the same 0 to 100 scale. This methodology allowed users to view how each candidate was faring in each state on any given day, and to follow the trends over time. Another major component to the index included the measurement of sentiment based on issues. Three specific topics were initially chosen by the organizations to gauge candidate approval. These included the economy, health care, and defense and foreign policy. Candidates again were ranked comparatively based on tweeted sentiment on those specific issues. Over time, the index added abortion, education, energy and the environment, gay rights, immigration, retirement, taxes, and terrorism to the list of monitored issues.

As a corollary to the extensive analysis of voter sentiment, Twitter added a political engagement map to help users better visualize sentiment. The map was based on responses by users to individual tweets originating from the candidates’ official Twitter accounts, rather than that of the index, which measured organic content directly generated from users. In addition, the results of this measurement were broken down by state and added to an interactive map. Twitter selected tweets from each candidate and ranked the level of engagement by users surrounding that tweet. The results were graphically charted, using a bar that changed in size—the higher the engagement, the longer the bar. When broken down by state, users could see the top five issues positively associated with the tweets from each candidate. For example, energy and the environment, the economy, taxes, retirement, and foreign affairs were the top five issues for candidate Romney in Ohio. Conversely, gay rights, taxes, the economy, education, and retirement were the issues on which candidate Obama had the highest level of engagement in the same state.

Prior to Election Day 2012, most major media outlets considered the race too close to call. Traditional polling seemed to show Obama as the clear favorite. A week before November 6, 2012, the Twitter Political Index showed Barack Obama with a rating of 32 to Mitt Romney’s 28, suggesting that the media’s assessment of voter sentiment

was more accurate. However, by the time voters went to the polls, Barack Obama’s rating had jumped to 74 and Mitt Romney trailed with a rating of 59. Barack Obama won the election with 51 percent of the popular vote to Mitt Romney’s 47 percent, a margin much closer than that of the Twindex. The Twitter Political Index ended direct comparisons between President Obama and Mitt Romney on December 4, 2012. However, individual measurement of sentiment of each political ticket and sentiment surrounding major political issues continue to be assessed and ranked. The consortium has not announced plans to change or end the index at this time. Given the steady rise in the use of social media, it is realistic to expect this index, or an evolved version of it, to continue well into the future.

Twitter

Twitter is a Web application for microblogging, or publishing miniposts called “tweets,” that are limited 140-character messages. Users of Twitter, or “tweeters,” tweet text as well as pictures and links to relay information. They can include keywords, called “hashtags” and indicated with the “#” sign (with no space) before a keyword. This hashtag allows anyone using Twitter to find any tweet that contains the hashtag for which they

search. Twitter is accessible through Twitter.com and through mobile media applications on smart-phones and tablets.

Twitter has its own language; a tweeter creates and manages a tweet in the following way:

- **@username:** Tweeters use the symbol “@” followed by a Twitter username to direct a tweet to another tweeter.
- **RT:** A tweeter can “retweet” or repost tweets that other tweeters have posted.
- **Quote tweet:** This action will put quotation marks around a tweet for a tweeter to repost or add to the message.
- **DM:** Tweeters can “direct message” or privately message each other through Twitter.
- **#keyword(s):** Tweeters can use a hashtag and a keyword within a message to help categorize tweets and help other tweeters to see these tweets.
- **Favorite:** By clicking a star icon in another tweeter’s post, a tweeter can bookmark, or save, a specific tweet. This tweet is then saved in a personal “Favorite” feed.

These actions can help a tweeter create more effective messages and communicate with targeted audiences. Tweets are public by default and are published in follower’s Twitter “feeds,” or a list of tweets published by the tweeters that an individual is following. Tweeters can also set their accounts to private so that they approve their followers and thus protect who sees their tweets. Tweets can also be directly sent from the tweeter to one follower as a direct message; this acts like a 140-character e-mail system.

In March 2006, software engineer Jack Dorsey sent the first official tweet from the podcasting company Odeo, where Dorsey had developed the concept with support from Noah Glass, Florian Weber, and others. Soon thereafter, Dorsey, Evan Williams, and Biz Stone created Twitter.com and hired other social media experts to establish and expand the new San Francisco-based social media company. In April 2007, users of Twitter published more than 2 million tweets a day, and by January 2010, tweeters were publishing more than 10 million tweets a day. Twitter had 200

million active users by March 2013, and is now a medium for tweeters to virtually gather during iconic and memorable moments, such as the passing of Apple cofounder Steve Jobs, or to mobilize for political activity, such as the U.S. political movement called the Tea Party.

Beneficial Uses

Twitter has allowed tweeters to create virtual relationships with individuals with whom they might not otherwise communicate. Twitter is used by social movements to allow the once voiceless to publish their opinions and communicate with others. Twitter also allows for international communication during events. For example, individuals involved in the revolution in Egypt, elections in Iran, and riots in London tweeted about what they were seeing, becoming citizen journalists who reported what they witnessed to anyone who accessed their Twitter feed or who searched for their hashtags. Twitter is also being used during natural disasters, such as Hurricane Sandy, which hit the east coast of the United States in 2012; individuals who did not have access to the Internet and were geographically confined because of flooding used the Twitter application on their mobile phones to connect with others and thus access information and call for help. For example, former Newark Mayor and New Jersey Senator Cory Booker (@CoryBooker) used Twitter to respond to citizens who needed help during the hurricane and to keep Newark citizens informed after the storm. On November 2, 2012, after the hurricane hit, Booker tweeted, “Delivering blankets and came upon a house with a carbon monoxide detector going off. Called fire dept. Please don’t use stoves to heat.”

Because of their public status and the number of individuals using Twitter, most news stations and journalists tweet, sending out headlines and breaking news. In fact, celebrities and politicians also tweet to communicate with their fans and followers. Social, political, and medical advocates use Twitter to publish information like events and research findings, as well as daily tips and briefs that these advocates believe will benefit their followers.

Twitter and U.S. Presidential Elections

Twitter is an important tool for U.S. political communication. Through Twitter, candidates can

engage the electorate in political discussions and U.S. citizens can voice their opinions. In addition, candidates provide their followers a firsthand report of current events related to their campaigns when they tweet pictures, links to speeches, and information regarding their views on issues. Twitter has become an organizational tool to gather political support.

In 2008, then U.S. presidential candidate Barack Obama began to use Twitter as a social media tool for his campaign. Obama's campaign team created a social media network that linked all major social media accounts to publicize activity on his campaign Web site. Obama's tweets included pictures of campaign activities and of him with his supporters, links to Web sites about his events, and text-based messages about campaign events and progress. His Twitter feed helped to provide information for a grassroots social media campaign and to move people to action on his behalf, such as to encourage supporters to donate, vote, and retweet his messages. As a result, Obama's campaign raised significant amounts of money from a large number of people who made small contributions. His campaign credits Twitter as one of the essential social networking tools to help inform followers on how to donate and to recruit supporters to further Obama's campaign messages.

In 2012, both candidates for the U.S. presidency, incumbent President Obama and Republican nominee Mitt Romney, maintained Twitter accounts as part of their campaigns. Obama's campaign team used @BarackObama, and Romney's campaign used @MittRomney. Both @BarackObama and @MittRomney's tweets included comments from the candidates, pictures of the candidates at events and with their supporters, links to online articles and campaign Web sites, and messages with campaign appearance information. Both candidates also used Twitter to indirectly debate with each other through pointed messages. For example, on October 22, 2012, Romney tweeted "Attacking me is not an agenda. #CantAfford4More." Obama tweeted on October 25, 2012, "RT if you agree: Mitt Romney's severely conservative views are a disaster for women that we can't afford in the White House."

Both campaigns tweeted throughout the campaign and gave readers messages that they could

then retweet to their followers. The retweet reaches many more people than just the followers of the candidate. In fact, the viral capacity of a tweet far outreaches the days of traditional word-of-mouth because it exceeds geographical boundaries and allows tweeters to forward messages around the world.

Twitter also allows the electorate to catch glimpses into the candidate's lives. A tweet may contain information about @MittRomney watching the Superbowl, or it may contain a photograph of @BarackObama with First Lady Michele Obama on a date. Twitter is useful for politicians to share information that traditional media outlets cannot report or to which they do not have access. Also, politicians can speak directly to the audience before speaking to the media. For example, on November 6, 2012, the day before the U.S. election, President Obama tweeted, "We're all in this together. That's how we campaigned, and that's who we are. Thank you. —bo." On November 10, 2012, three days after the election and his loss of the U.S. presidency, Governor Romney tweeted, "From the bottom of our hearts, Ann and I thank you for your support, prayers, efforts, & vote. We are forever grateful to every one of you."

During the 2012 presidential election, participation during the televised presidential debates increased and tweeters began to analyze what each candidate said. One example of this is the response to Governor Romney's comment that, during his term as governor of Massachusetts, he wanted to hire qualified women and he was handed "binders full of women," meaning binders of resumes of women who were qualified to serve on his cabinet. After he said "binders full of women," the hash tag #bindersfullofwomen started trending. Related memes, or cultural references or items (such as photographs, video clips, or sayings), passed virally from one person to another. Similarly, Twitter allowed users to spread information in real time as the candidates debated. Twitter proved to be an organizing tool for both supporters and critics to publicize rhetorical blunders and successes.

Twitter and Politicians

During President Obama's first term at the White House, his staff organized a Twitter town hall meeting that was moderated by Twitter founder

President Barack Obama tweeting his responses in a live Twitter question-and-answer session conducted from the White House on December 3, 2012. He is surrounded by members of his staff, including Director of Online Engagement Kori Schulman, Director of Digital Strategy Macon Phillips, Press Secretary Jay Carney, and Senior Advisor David Plouffe. During the 2012 presidential campaign, Obama had more than 20 million Twitter followers, compared to 1.2 million for Mitt Romney.

Jack Dorsey that established the White House Twitter feed (@WhiteHouse) as a source of information for U.S. citizens. @WhiteHouse tweets information about upcoming legislation, links to more information about legislation, pictures, and text-based messages that help to promote transparency from the White House.

Congressmembers are also tweeting. For example, on August 28, 2012, Congresswoman Michele Bachmann (@MicheleBachmann) tweeted, "Congress returns from August Recess/district work on Sept 10. What do you feel is the most pressing issue for the rest of the 112th Congress?" Similarly, on November 25, to encourage interaction from constituents, Congressman Steve Pearce (@RepStevePearce) tweeted, "Remember to contact my office if you're interested in inauguration tickets!" Congressman Gregory Meeks (@GregoryMeeks) also

tweeted, "Remember to tune into @meetthepress today for my thoughts on the #Sandy recovery effort and other important topics. DC/NY time 10:30–11:30 A.M." On November 8, 2012, in response to the re-election of U.S. President Obama, Congressman and Speaker of the House John Boehner (@SpeakerBoehner) tweeted, "ObamaCare is law of the land, but it is raising costs & threatening jobs. Our goal has been, and will remain, #fullrepeal."

Congressional use of Twitter is important because these tweets encourage communication and interaction between representative and citizen and the transparency of Congress. Through Twitter, U.S. citizens can follow the daily official business of the U.S. government and can respond to their representatives if they are unhappy with the representatives' stance or vote. In return, representatives can concisely share links, promote

ideas, and alert citizens to events. Most congressional tweets are informational, but Congress will also promote their positions in hopes for support from their constituents and other party members. Twitter is not a perfect place to directly contact Congress, but the venue serves as a starting place to develop ideas, gain support, and lead citizens to additional information about issues and events.

A Web site was established by a grassroots effort to encourage Congress to tweet. The Web site, Tweet Congress (tweetcongress.org), helps constituents find their state representatives and senators. If a senator or representative is not tweeting, the Web site allows a person to sign a petition to encourage that representative to communicate via Twitter.

Tweeters must be careful to know how to use Twitter. An uneducated or careless individual may regret accidental and inappropriate tweets. One of the most infamous examples came from former Congressman Anthony Weiner. While tweeting sexually motivated photographs to a follower, he accidentally tweeted publicly instead of privately, and a photograph was published to all of his Twitter followers. Since the incident, Weiner has resigned. His mishap reminds public figures to be careful about what they tweet because inappropriate tweets could end their public service careers.

International Political Use

International government leaders also use Twitter to communicate. Two of the most notable world leaders who use Twitter are United Kingdom Prime Minister David Cameron (@David_Cameron) and Chile's President Sebastián Piñera (@sebastianpinera). Piñera also commissioned his cabinet members to create Twitter accounts to help inform Chileans of government actions and events. International leaders must be careful of what they tweet. In May 2012, Venezuela's President Hugo Chavez verbally attacked Colombian President Alvaro Uribe Velez, tweeting that he was an "assassin." These tweets can create trouble for diplomats, and tweeting harsh sentiments is a concern for foreign relations. Some foreign ministers may not follow each other because of diplomatic differences.

Foreign leaders are also using Twitter to inform other leaders of their opinions about a decision.

For example, on September 19, 2012, the U.S. ambassador to the Russian Federation tweeted, "We regret this decision. MT @MFA_Russia has notified the US that USAID must stop operating in Russia from October 1." The Russian Federation government did not respond well to this tweet because it does not like the public display of criticism. The use of Twitter in foreign relations is new for many governments who may censor their citizens' use of media, including access to social media outlets like Twitter.

Tweet for Change

As governments tweet more information, their citizens are using Twitter to organize social movements to change their political lives. Twitter and other social media venues have been used to create social change, for example, by citizens in Tunisia, Egypt, Libya, Yemen, Syria, Algeria, and Bahrain. Many countries followed via Twitter when Egypt experienced revolution on January 25, 2011, and some researchers credit Twitter and Facebook as tools that helped citizens organize the revolution. In Egypt's revolution, citizens contacted other people via social media to spread their dissent, and interpersonal relationships increased between Egyptian revolutionists and people outside Egypt. In this way, Twitter helped Egyptian citizens communicate to the world and to each other to build trust and confidence. They created political change and overcame government suppression. In the end, Egyptian President Hosni Mubarak resigned.

Twitter is changing the political landscape all over the world and is giving public opinion leaders and ordinary citizens a new outlet to express their sentiments in 140 characters or less.

Twitter Archiving Project, Library of Congress

The online social messaging system Twitter was founded in 2006, and has significantly grown since that time. With nearly half a billion registered users and hundreds of millions of tweets

sent each day, the service has become one of the most popular Web sites and social networking systems in existence. From its verified accounts for public figures to the role it has played in social upheaval, most notably major elections and the Arab Spring and its use as an identity authenticator for Web sites of all stripes, Twitter has become more than simply a way to share 140-character messages. The service has become an integral part of public relations and marketing campaigns, an organizing tool for groups and individuals, and a daily routine for millions of people around the globe.

The significance of Twitter was recognized early on in the popular press. Academic circles developed software designed to mine tweets for socially significant patterns and business purposes. The U.S. Library of Congress’ mission is to acquire, preserve, and provide access to knowledge and the record of America’s creativity for Congress and the American people. In support of this goal, in April 2010, the Library of Congress signed an agreement with Twitter that would archive tweets posted between the network’s inception in 2006 through April 2010. Only tweets marked public would be included. Twitter accounts default to displaying tweets publically, and early users were often less savvy about issues of privacy. This meant that early on, the majority of tweets were public, with users increasingly making use of private tweets and private accounts (permission is required to follow or view the tweets of a private account).

The agreement stipulated that Twitter would donate all public tweets from Twitter services, representing approximately 21 billion total tweets. The collection of tweets is bound by a set of rules that attempt to prohibit commercial use or that significantly impinge on the loose level of privacy that might reasonably be expected by Twitter users. Among the stipulations are that the Library of Congress agreed to make portions of the collection available to “bona fide” researchers six months after the material was transferred to the Library of Congress. Researchers who are given access to the collection are required to sign an agreement stating that they will not redistribute the information or use it for commercial purposes. Further, the library agreed not to post significant amounts of tweets to a Web site or in a format that

is easily downloaded to guard against commercial harvesting of tweets and related information.

The original agreement for tweets between 2006 and 2010 was fulfilled on February 28, 2012. The data was compiled by a third-party company called Gnip, and was delivered in three compressed files totaling 2.3 terabytes of data. Besides the text of the tweets, there were over 50 fields of metadata for information such as time and location. The agreement between Twitter and the Library of Congress continued beyond 2010, and starting in February 2011, current tweets were also transferred. According to the Library of Congress, as of December 1, 2012, the library housed over 150 billion more tweets, for a total tweet count of over 170 billion, comprising more than 133 terabytes for two compressed copies.

Different from its other digital collections, this is the only set that the Library of Congress receives in a live, continuous stream. As of May 2013, Gnip is still the primary agent responsible for delivering tweets to the Library of Congress. Gnip receives the tweets in real time, but segments the data and organizes it, delivering segments consisting of one hour of tweets at a time. In October 2012, the Library of Congress received nearly half a billion tweets per day, and utilized a number of platforms and software to organize, store, and back up the information. The library was also converting the 2006 to 2010 data into the same one-hour format currently used for accepting tweets. The Library of Congress does not yet provide traditional access to the collection, but is attempting to avoid the overhead of even simple searches (a basic text search can take over 24 hours) by employing parallel computing approaches.

As of January 2013, the Library of Congress had received over 400 requests from researchers seeking access to the collection for a variety of purposes, including the study of citizen journalism and elected officials' communications, tracking vaccination rates, predicting stock market activity, and how hashtags are used and mutate over time. Spurred by interest in the Library of Congress project, Twitter announced that it would make Twitter users' tweets available by search, a difficult technological goal.

Some have argued that the agreement between the Library of Congress and Twitter is at least in part the result of a push by American President

Barack Obama's administration to increase transparency in government and politics, to promote social awareness via popular outlets, and as a pilot project for making the archives of various government agencies available. Others have noted the inherent violation of personal privacy that occurs when personal communication content is reframed as widely available public property, without the knowledge or the permission of those who generated it. Researchers seek ways to leverage the collection of tweets to track the movement of political and popular ideas through social networks, including the study of marketing, political communication, interpersonal relationships, and a vast array of other subjects ripe for data-mining projects. The full possibilities that a collection this size provides may not be known for years.

Twitter Diplomacy

Twitter diplomacy refers to the use of social media by nations as tools for furthering diplomatic and foreign policy goals. This term is also commonly referred to as e-diplomacy, twiplomacy, and digital diplomacy. The use of social media by diplomats has opened communication between policymakers and citizens. These tools, especially Twitter, provide diplomatic missions

The U.S. Department of State held its first Tweetup at the 2013 International Women of Courage Award Ceremony at its headquarters in Washington, D.C., on March 8, 2013. In attendance were U.S. Secretary of State John Kerry, First Lady Michelle Obama, and Mrs. Teresa Heinz Kerry, pictured here together with participants in the event.

with direct access to citizens, both inside and outside of their countries. This communication often bypasses state and media filters, potentially enabling countries to more effectively influence foreign audiences and achieve diplomatic objectives. Likewise, citizens are afforded the ability to interact with diplomats in a two-way Web 2.0 fashion. The U.S. State Department describes this evolution of diplomacy in the social media age as having advanced “state-to-state diplomacy” to now include “state-to-people, people-to-state, and people-to-people.”

Twitter diplomacy is an international phenomenon. According to the July 2012 Twiplomacy Study, 264 heads of state and government in 125 countries around the world had an active presence on Twitter in 2012. Although the use of e-diplomacy by the United States is said to have begun during the second Bush administration, the use of Twitter diplomacy was greatly advanced through the 21st Century Statecraft

initiative during the first Obama administration, under Secretary of State Hillary Clinton. Currently, the State Department purports to have more than 2.6 million followers across its 301 official Twitter accounts that tweet in 11 languages. As of May 2013, the department’s official Twitter page (@StateDept) had posted about 29,000 tweets and was followed by more than 520,000 people. These numbers are likely to keep growing because social media continues to be employed by U.S. ambassadors such as Susan Rice and John V. Ross, who together have close to 400,000 Twitter followers.

Twitter diplomacy has been prominent in a number of recent events around the world, notably the protests that occurred in the Middle East between 2009 and 2011. For instance, seeing the importance of Twitter and its use by protesters during the 2009 summer protests in Iran, the U.S. State Department asked the social-networking site to postpone a previously scheduled routine

maintenance of the site, which would have rendered it unavailable for 90 minutes. Similarly, U.S. Ambassador to Syria Robert Ford kept the public informed about happenings during the Syrian protests of 2011 by posting images and messages on Facebook, with messages reaffirming that the United States wholly supported Syrians' rights to protest. Ford's postings were directly followed by real-time public reactions from citizens from the Middle East and around the world. Diplomats from other countries, such as Italy's Foreign Minister Giulio Terzi, used Twitter to condemn violence in Syria. Other nations employ digital diplomacy in proactive, not reactive ways, such as the extensive use of online and social media employed by Queen Rania of the Hashemite Kingdom of Jordan, who has been inviting both citizen and visitor social media engagement for several years as a strategy for preventing sectarian division within the kingdom, and outsider misunderstanding of the country.

Challenges

As with any new communication technology, the use of social media for foreign diplomacy has spurred concerns and risks. Challenges diplomats face with Twitter diplomacy are similar to those confronted by mainstream journalists. While social media enables speedy, transparent, and dynamic communication that presents new opportunities in the diplomatic arena, information transmitted via social media may involve sensitive diplomatic negotiations between delegates of nations. This information may be factually inaccurate, culturally insensitive, or may discuss issues traditionally kept to behind-the-scene official channels. Furthermore, comments made by diplomats and ambassadors may contain their subjective or personal opinions on foreign issues and policy, rather than the official positions of their countries. These comments can adversely affect how parties settle or mediate disputes and make arrangements, and result in unnecessary misunderstandings between nations.

For example, in April 2013, the Twitter account of the U.S. Embassy in Cairo, Egypt, tweeted a link to a clip of the *The Daily Show With Jon Stewart* that mocked Egyptian President Mohammed Morsi and his administration's actions regarding the arrest of an Egyptian satirist. Following

a complaint from the office of the Egyptian president on Twitter, the U.S. Embassy's account, which had a track record of controversial Twitter postings, was temporarily shut down.

Another challenge is a lack of training in proper use of social media for diplomacy. In particular, some leaders may not recognize the rules of conduct of Twitter diplomacy. These could include proper etiquette for sending information, and effective techniques for listening to, and engaging with, the public and foreign nations. Some leaders may fail to recognize the power of social media and the Internet.

With social media features such as hashtags, "likes," and shares making it easy to encounter and find information, inappropriate and careless posts made by government authorities can be instantly shared with millions of users or retrieved by the press. Social media could continue to improve the efficiency of communication between diplomats and citizens. However, the potential benefits of these tools are not without limitations and potential drawbacks.

TwitVid.com

While Twitter, as a microblogging service, has already played a big role in social media in politics, it has limited users to 140 characters in each tweet. TwitVid.com offers a social video-sharing network connected to the real-time and up-to-date power of the Twitter network as a means of sharing visual material such as video and screenshots from mobile media like iPhones, Androids, and BlackBerrys. It may play an increasing role in the kind of citizen journalism and user-generated content activities that make social media such exciting and unpredictable players in emerging political and cultural arenas.

Because TwitVid.com only needs a Twitter account to log in, the video-sharing service already has a head start on its competitors. TwitVid allows users to upload videos over one gigabyte; there is no restriction on the running time of the video. TwitVid instantly displays all tweets credited to a particular video. Other common Twitter features such as retweeting (forwarding a tweet or the video), sharing, and replying to a video are supported by TwitVid. It is possible to share videos from all mobile devices and computer interfaces, and TwitVid has the ability to share videos in real time. In recent years, other functions from well-known social networking sites have been included in the TwitVid interface. These functions include Facebook “likes,” video statistics, categorizing, and recommendations as seen on video platforms such as YouTube or Vimeo. TwitVid runs mobile versions of its app on Android, iPhone, and BlackBerry. This service makes it easy to upload and share both videos and photos from any device to the TwitVid service, but also to Twitter and Facebook, sharing both existing content and real-time feeds.

After launching in 2009, Twitvid saw its service grow in 2011 to 12 million monthly unique users, and more than 30 million unique video views per month. After TwitVid.com replaced 12Seconds.tv as TweetDeck’s default video platform in 2010, TwitVid announced growth of 100 percent a year. TweetDeck is a dashboard application for managing social media accounts or platforms like Twitter and Facebook. In 2012, Twitvid had more than doubled the number of video views it served

over 2011. The video sharing network counts views in the range of 70 million, over 15 million unique visitors, and had 200 million active users by March 2013.

In the first half of 2012, the social video network made several acquisitions, indicating a possible strategy change or product announcement. The first acquisition brought the team from Frugalito to TwitVid. This daily deals aggregator was acquired to use its know-how and knowledge, not necessarily for the platform. The second acquisition was treated the same way. Cull TV, an independent music video-sharing site, offers a catalog of approximately 3 million music videos. TwitVid is mostly interested in the work Cull TV did in figuring out how to prioritize and recommend content out of long-tail video, and their combination of manual curation and algorithms to find the most relevant content.

In June 2012, TwitVid announced its rebranding as Telly. In its announcement TwitVid explained the rebranding in light of the abundance of video that TwitVid and many other video platforms offer. Telly gives the TwitVid platform the possibility, after providing a video upload and sharing service for Twitter through mobile apps, integrations, and the Web, of offering a place to collect and share videos, and to discover new videos to watch through seeing what social connections watch, talk about, and like.

Telly will be a hybrid platform, spun from a number of recently acquired technological threads, all helping to make video data more accessible and more useful, and will provide recommendations and personalization. Telly will include all features and concepts that were included in TwitVid, such as uploading and sharing videos. However, the new platform will also offer more video creation and editing tools to add filters to videos or include soundtracks.

U

Ubicomp

Ubicomp (ubiquitous computing), also referred to as pervasive computing or ambient computing, is a model of human–computer interaction involving information and communication technologies (ICTs) woven into physical and social environments. The term *ubiquitous computing* was originally coined by Mark Weiser in the 1980s when he was leading the Computer Science Laboratory at the Xerox Palo Alto Research Center (PARC). Weiser envisioned computers that are integrated “seamlessly into the world” and thereby can become a natural part of everyday life. In 1991, Weiser presented his vision of ubiquitous computing in the article “The Computers for the 21st Century” published in *Scientific American*. More than 20 years have passed since the publication of the seminal article, and the conceptual model of ubicomp has been actively deployed, with important implications for political behavior.

Weiser questioned whether “personal computers” were truly “personal,” noting that they fell short of blending into people’s everyday lives. Weiser analyzed the problem at two levels: intrapersonal and interpersonal. First, at the intrapersonal level, those computers were “approachable only through complex jargon that had nothing to do with the tasks” that users would want to achieve. Weiser observed that such a condition

was “analogous to the period when scribes had to know as much about making ink or baking clay as they did about writing.” Noting that when people learn about and know something very well, it is natural for people to “cease to be aware of it,” Weiser argued that computing should free users’ attention from the machine and allow the users to better focus on the task. At the interpersonal level, Weiser emphasized how personal computers, dominating the center of users’ attention and posing barriers to interpersonal interaction, introduced “unhealthy centripetal forces” into human collaboration. Weiser predicted that computers vanishing into the background would “make individuals more aware of the people on the other ends of their computer links” and thereby enhance the socialness of computer-based collaboration.

It is important to note what technological practices do or do not qualify as ubicomp. Making computers portable (e.g., laptops) does not necessarily integrate them into the environment seamlessly, as articulated in Weiser’s statement: “Even the most powerful notebook computer, with access to a worldwide information network, still focuses attention on a single box.” Emphasizing that technological practices based on mere enhanced portability would not constitute ubicomp, Weiser specified the basic requirements for ubicomp (namely, technological

practices that can make computers invisible and “disappear into the background”) as follows: (1) low-cost, low-power computers that people can use anytime, anywhere; (2) software applications that can track people’s locations and allow people to collaborate on shared tasks; and (3) a wireless network that can accommodate and integrate the multiple computers and applications as an organic whole.

Weiser further noted that ubiquitous computers should be embedded in “artifacts for use in everyday life.” While acknowledging that such devices should be able to come in assorted forms and sizes, Weiser proposed three prototypes for ubicomp devices: tabs (inch-scale machines), pads (foot-scale machines), and boards (yard-scale machines). Tabs, as the smallest of the three, were modeled after “tiny individual notes or PostIts.” Pads, on the other hand, were conceived as “something of a cross between a sheet of paper and current laptop and palmtop computers” that could be easily grabbed and used, just like “scrap paper.” Boards, the largest of the three, were envisioned as a digital equivalent of a whiteboard. As Maria R. Ebling and Mary Baker note, these three scales of computing machines have been embodied in “smart” devices such as smartphones (tabs), tablet appliances (pads), and interactive whiteboards (boards).

Ubicomp practices enabled by smartphones, pad-like appliances, and their applications (abbreviated as apps), as Weiser envisioned two decades ago, allow people to use computing devices without being dominated by them. This trend has important implications for political life. With enhanced capacity of sensing/tracking/recording time and location, these technologies enable users to instantaneously search, create, organize, and share various modes of information. In line with Clay Shirky’s argument, ubicomp can provide platforms for mobilization of collective action and stimulate political participation by allowing people to “share, then gather,” as opposed to the “old order of group activity” in which people used to “gather, then share.”

Udall, Mark

Mark Udall is the senior Senator in the U.S. Congress from Colorado. He was first elected in 2008 to the Senate. He is a member of the Democratic Party. Mark Emery Udall was born July 18, 1950, in Tucson, Arizona, to Patricia J. Emery and Morris “Mo” Udall. His father served in the U.S. House of Representatives from the 2nd District of Arizona (1961–91), and was a candidate in 1976 for the nomination to the Democratic Party ticket for the presidency. The Udall family has been very involved in politics. Beside his father, Udall’s first cousin is Thomas “Tom” Stewart Udall, junior U.S. Senator from New Mexico. His second cousin is Senator Mike Lee of Utah, and his uncle was Stewart Udall, the former secretary of the Interior. While all of these political relatives are Mormons, Udall does not list a religious affiliation.

In 1968, Udall graduated from Canyon del Oro High School in Tucson, Arizona. He then entered Williams College in Williamstown, Massachusetts. He completed a B.A. in 1972. Udall married University of North Carolina graduate Maggie L. Fox, with whom he has two children. Their home is in Eldorado Canyon, Colorado. She later earned a masters in education from the University of Colorado, and a J.D. from the Northwestern School of Law with an emphasis in environmental law and Native American natural resources law.

Her early career was teaching on Navaho and Hopi reservations in Arizona and New Mexico. She worked with the Colorado Outward Bound School, where Udall also served 10 years as the school's director. She later worked for the Sierra Club, serving as its deputy executive director for five years. She has been actively involved in issues such as climate change, energy, western public lands and water, Native American resources, and agricultural reforms. Her other positions have included former president of America Votes and president and CEO of the Alliance for Climate Protection.

U.S. House of Representatives

In 1996, Peggy Lamm, a Democrat, resigned her seat in the Colorado House of Representatives. Her district was the 13th district, which encompassed the community of Longmont and parts of southern Boulder County in which Udall was living. Udall ran and won the seat. In 1998, he won the Democratic Party nomination for the 2nd Congressional District of Colorado. He had previously served a single term in the Colorado House of Representatives. The nomination was for the seat of incumbent David Skaggs, who was retiring. The general election became a tight race that Udall barely won. His opponent was Bob Greenlee, the Republican mayor of Boulder, Colorado. The final vote put Udall over the top with 50 percent of the vote to 48 percent for Greenlee.

In the elections of 2000, 2002, 2004, and 2006, Udall won re-election without significant opposition. Political scientists who studied his district found that he was very representative of the overwhelming majority of the people in the district.

Udall's record in the House of Representative is solidly liberal to centrist on some issues. In 1998 he voted against barring transporting minors to have an abortion. In 2000, he voted to allow partial birth abortions. In 2001, he voted not to make it a federal crime to harm a fetus while committing other crimes. He also voted in 2001 to support funding for family planning through U.S. foreign aid. In 2003 he voted to allow human cloning for reproduction and medical research. In 2004, he again voted against federally criminalizing harming a fetus during the course of committing a crime. In 2005, he opposed attempts

to outlaw transporting minors to an abortion clinic. In 2005, he also voted in support of human embryonic stem cell research from fetal material. His voting record on abortion and environmental issues has put him into a category that many would call staunchly liberal.

Others who have examined Udall's voting record see him as more mainstream, especially on economic and defense issues. He has supported the military and defense industry. He was able to acquire research money for Colorado defense companies. On the environment his positions reflect those of his wife. He has been an advocate for alternative fuels and for strong protections for the environment. In 2000, he proposed turning the former Rocky Flats nuclear weapons facility into a wildlife refuge, and the Rocky

Senator Mark Udall (left) stands atop a prototype wind turbine during a visit to the National Wind Technology Center in Louisville, Colorado, in March 2013. The visit was documented in a number of photographs posted on Senator Udall's Flickr account.

Flats National Wildlife Refuge Act became law in 2001. He also supported renewable energy initiatives. After 9/11, he opposed the USA PATRIOT Act as a threat to personal liberties. He has also opposed indefinite detention of American citizens. His amendment to the National Defense Authorization Act for fiscal year 2012 was rejected.

Udall served on several committees and joined a number of caucuses while serving in the House of Representatives. He was also a member of the NATO Parliamentary Assembly, which brings together members of parliaments (and the U.S. Congress) from NATO member countries in order to promote support and understanding of NATO. He was also a member of the Democratic Homeland Security Task Force.

U.S. Senate

Wayne Allard, the incumbent Senator from Colorado, announced on January 15, 2007, that he would not seek a third term. His retirement from the Senate and refusal to seek a third term was to fulfill a pledge he had made when first elected that he would only serve two terms. Udall entered the Democratic primary for the nomination. He gained the nomination unopposed. His opposition in the general election was Republican nominee Bob Schaeffer, a former U.S. Representative.

Schaeffer had been defeated in his 2004 bid to win the Republican nomination for the U.S. Senate seat held by Ben Nighthorse Campbell, who was retiring. In a brutal primary, Schaeffer was overwhelmed by Coors Brewing magnate Pete Coors. In the general election, Coors was defeated by Democrat Ken Salazar.

Clearing the air about anything that could be an "October Surprise," Udall told the *Rocky Mountain News* in January of 2008 that he had been found in possession of marijuana in 1972. He had subsequently pled guilty to possession, and his sentence was a year's probation. The revelation was not enough to prevent either his nomination or his election.

During the election, in which over \$10 million was spent attacking Udall, Schaeffer was tarred with the Jack Abramoff scandal, President Bush's energy plan, and accusations from environmental groups that he was in favor of polluting the environment. These and other accusations aided Udall, who won the seat with 53 percent of the vote.

During his time in the Senate, Udall has attempted to solve problems by reaching across the aisle to Republicans. This reflects his willingness to work with others for the good of the country. Among his environmental achievements have been bills to address beetle infestations in western forests and the fire hazards that the beetles create. He has also promoted clean energy legislation, high technology and the aerospace industry, consumer credit protection, and health care for workers and retirees who worked at U.S. nuclear facilities. Udall has promoted with other Senators the adoption of smart budgeting tools and a pay-as-you-go rule for federal spending. He has been opposed to the easing of the national debt ceiling.

Since entering the Senate in 2009, Udall has served on a number of Senate standing committees. Among the "little legislatures" to which he has been assigned are the Committee on Armed Services, which includes serving on its Subcommittee on Emerging Threats and Capabilities, Subcommittee on Readiness and Management Support, and Subcommittee on Strategic Forces. His service on the Committee on Energy and Natural Resources has included serving as Chairman of the Subcommittee on National Parks, the Subcommittee on Public Lands and Forests, and the Subcommittee on Energy. He is also serving on the Special Committee on Aging.

Caucus memberships held by Senator Udall include the Congressional Fitness Caucus, Sportsmen's Caucus, Renewable Energy and Energy Efficiency Caucus (of which he is the cochair), and the Parkinson's Disease Caucus, which he also cochairs. His membership in this latter caucus is doubtless due to the fact that his father, "Mo" Udall, died from Parkinson's disease. He is also a member of the International Conservation Caucus, which was founded in September 2003 in the Senate as a bipartisan organization. It is based on the conviction that the United States needs to promote the conservation of natural resources both at home and abroad.

Social Media

During his 2008 Senate campaign, Udall used a campaign Web page to enlist supporters, who would sign in with their e-mail and zip code. Links to volunteering and contributing to his campaign were made readily available to visitors

to his campaign page. Other links took visitors to his biography, his “bipartisan record,” and a blogging and media center. Photos and videos were also available to be used as campaign tools.

Since being elected to the Senate in 2008, Udall has increasingly used social media. He has a Web site with links to blogs, news sites, e-mail, audio, video, and op-eds. In addition, there are links to Facebook, Pinterest, Twitter, LinkedIn, Digg, Tumblr, Reddit, StumbleUpon, and Google+. There is a search function for the Web site, as well as a search function for legislation. Another link allows for e-mail contact. Another link is to a “news room,” which leads to both news items and blogs.

The Senate page Udall uses (markudall.senate.gov) is loaded with links to his biography, issues, matters of concern to his Colorado constituents, and another “news room” with links to blogs, news, video, audio, op-eds, and a press kit. The page can be shared with Facebook, Pinterest, Twitter, LinkedIn, Digg, Tumblr, Reddit, and StumbleUpon. Individual icons allow a visitor to use RSS Feeds, YouTube, Flickr, and Facebook. All of these links help people interact with Udall to inform him of their views or support him in his legislative work.

Unemployment

During the period of recession from 2008 to 2011, many countries worldwide were faced with a shortage of jobs and growing unemployment. Many people lost their jobs and experienced a drop in income. Social media played an important role, both as a channel of sharing information about job openings, and as a means of earning money.

Social Media and Job Searches

A considerable part of job searching now takes place online via social media platforms, where job seekers can interact with employers and vice versa by sharing a profile or posting a vacancy. In social media platforms, the flow of information about vacancies is faster. A human resources specialist in a company or agency may post a relevant message to their “friends,” who then spread it to their contacts. Thus, information about a vacancy is quickly distributed and may experience a snowball effect. However, the structure of connections of recruiters and human resources specialists might limit the possible circle of recipients to friends, friends of friends, and perhaps a few more. It means that those who do not see information about these vacancies are excluded from the discourse, and they have lower chances of finding out about a job.

Wide use of social media platforms expands networks of connections, but can determine who receives information about a vacancy and

when; this in turn may determine who gets a job and who is left unemployed, which will have an impact on the distribution of earnings and overall inequality in a society. Economic sociologist Mark Granovetter, in his writings on the strength of weak ties, emphasized their importance for the job search. His research proved that weak ties work better for getting a job than strong ties, meaning that “friends of friends” would receive a job offer from a company they are indirectly connected with through their contacts with higher probability than close friends or relatives of current employees.

In his recent public lectures, Granovetter claimed that social media are attractive to people because comprehensive knowledge of their social networks is limited by time constraints. On one hand, people are more connected to larger communities through weak than strong ties because one’s close friends know each other, forming a closed circle. Weak ties are less likely unacquainted between each other, thus they move in different circles from the circle of close friends and from one another’s. Social media in this respect can foster reviving, maintaining, and creating weak ties.

A vital resource for the job search and posting vacancies is LinkedIn, where people create profiles with information about their education, employment history, skills, awards, honors, hobbies, and publications, and all other information that might be relevant to the potential employer. A huge number of companies and staffing agencies also have profiles on this social media platform, and are able to approach candidates with required qualifications using filters. LinkedIn also provides opportunities to join various communities and groups related to professional interests and industry sectors, which may also increase chances of getting a job offer.

Because it has become so easy to find suitable candidates through social media, search costs for companies and recruitment agencies have been reduced. This also means, in some cases, that there is a reduced need for long-term full-time employees, because employers may react to the economy’s ups and downs by offering more short-term project employment. This makes people on the labor market more vulnerable, and is likely to increase the number of days between jobs.

Social Media as Employment

Using social media as an environment for earning money is rather recent, and may be related to such work as social media marketing and journalism. Social media marketers are used by producers of fast-moving consumer goods or durables and by service providers (such as banks, insurance companies, and tourist agencies) for communicating their brands and goods with customers. Social media marketing specialists should be experts in creating and supporting the Facebook page of the brand or company, know how to attract and keep more followers of the page, and what news should be posted on it. This range of duties is comparatively new for marketing specialists who gained their experience working with traditional communication channels (television, printed media, and below-the-line activities), so companies often hire new specialists to take care of social media marketing and public relations. This work may provide opportunities for employment for younger workers who are often active social media users.

Social media journalism is another new type of occupation in the digital age. Most print publications or television channels worldwide have blogs, pages in social networking sites, or online forums, and they have employees whose duties are to support the online version of the edition and communicate with readers and viewers.

Drawbacks

Despite the above-mentioned positive impacts, social media can also bring some negative effects for job seekers. Recruiters warn candidates that they should be careful about postings on the Internet. Social media platforms like Facebook, Twitter, YouTube, or personal blogs may reveal much about a possible candidate and his or her private life. This may create numerous opportunities for damaging a job search or affecting a promotion. Hiring people with particular public online records may also put a company in legal jeopardy. Some employees have even been fired for something they wrote on Facebook or posted on Picasa. Thus, it can be assumed that unemployment might increase because of the incautious use of social media tools by employees, on one hand, and the strict policy of a company toward its reputation and image in social media, on the

other hand. The importance of connections on social media platforms is obvious, though online communication, interaction, or activities might be at risk of becoming less transparent because of the employers' hiring policies and corporate culture.

Psychological Impact

Another angle on the links between social media and employment is the combination of the real and the virtual in people's lives. One of the life satisfaction studies within the World Values Survey revealed that the users of virtual worlds are more satisfied with their virtual life than with real life. The unemployed and people with other challenges in their lives gain more life satisfaction from switching to the virtual world than from changing their real-life circumstances. In other words, an unemployed person may become happier by visiting a social media platform than from finding a job. Thus, problems in real life can cause more intense use of virtual platforms.

United Nations Global Pulse Project

According to recent studies, chatting online can assist in predicting the rise or fall of unemployment in real time. Many online users complain in social media about their financial situation, from cutting back on health care to deciding not to buy a new car. Such discussions can provide data on employment conditions before traditional government statistics.

The United Nation's (UN's) data initiative UN Global Pulse is a project for exploring innovative methods for combining new types of digital data with traditional indicators to track global development in real time. The project aims to provide economic information while it is happening to governments, social service groups, and policymakers so they can immediately respond to drops in employment, not months afterwards. This initiative of the UN is conducted in collaboration with the software firm SAS. The main idea is to define how social media and online user-generated content can be used to enrich understanding of changing job conditions. The project initiators aim to analyze the moods and topics present in unemployment-related conversations from the open social Web (blogs, forums, and news) and relate them to official unemployment statistics.

This exploratory project was conducted using the data on the United States and Ireland through analyzing online discussions over a two-year period, from June 2009 to June 2011. In both countries, social media were widely used and the economic crisis had a considerable impact on employment rates. According to the data provided by the U.S. Census Bureau, the unemployment rate in the United States reached double digits for the first time since the 1980s, dropping slightly from that peak to around 9 percent by 2012. According to EuroStat, the unemployment rate in Ireland was 5 percent in 2000, but it has risen since the economic crisis of 2008 to 15 percent.

Two specific research questions were raised in the study: (1) whether online conversations can provide an early indicator of impending job losses, and (2) whether user-generated content can help policymakers enrich their understanding of coping strategies employed by individuals. For answering these questions, the researchers used SAS's tools and technologies for the analysis of job-related, user-generated, unstructured text data. The methodology included assigning a mood score based on the tone of the conversations, for instance, anxiety, happiness, or depression. A number of unemployment-related documents dealing with other topics like housing or transportation were also quantified. It allowed for gaining insight into coping mechanisms.

This data was analyzed in two steps. First, the quantified mood scoring was correlated to the unemployment rate to discover main indicators that assist in forecasting changes in the unemployment rate. Second, the documents related to coping mechanisms also showed a significant relationship with the unemployment rate, providing some insights into the possible reactions of populations dealing with unemployment. Thus, the sentiments and topics were gathered from social media content, and then they were quantified and correlated with the official statistics on unemployment.

The researchers defined the relevant data from the various public Internet sources if they contained references to terms or phrases related to unemployment, such as "unemployed, fired, on the dole, and collecting unemployment." Then, the documents passed through a filtering process in order to clean the data of noise and to sort

documents by topic. The following topical categories related to coping mechanisms were used: housing, transportation, entertainment, consumer spending, bills, financial distress, nutrition quality, borrow/save money, education, health care, unemployment claims, and travel.

After conducting all steps of the analysis, the research team created “dashboards” for two countries with a visual representation of the findings. Such representation of the results allowed seeing and comparing the volume of conversations around unemployment, and coping mechanisms discussed with regard to unemployment. Also, time relationships between unemployment, conversation moods, coping mechanisms, and macroeconomic indications were included on the dashboards, showing patterns and predictions for the users. The dashboards contain over 28,000 documents for Ireland and 430,000 for the United States, covering the period from June 2009 to June 2011. Over a half of these documents were classified with regard to coping mechanisms.

The analysis has discovered that increased social media talk about various employment-related things, like postponing vacations, predicted growth of the unemployment rates in both countries. Correlation coefficients of mood scores with unemployment rates allowed for several predictive statements. For example, in the United States, depressed moods increase four months before a spike in unemployment (correlation coefficient is 0.489, with 95 percent significance level), and talk about loss of housing increases two months after an unemployment spike (0.634, 95 percent significance level). In Ireland, confused moods increase three months before a spike in unemployment (0.675, 95 percent significance level) while confident moods decrease two months before an unemployment growth (-0.407, 95 percent significance level), along with the increase in talk about travel cancellations three months after an unemployment spike (0.450, 95 percent significance level).

Conclusion

The initial project demonstrated the high potential of using social media data in addition to official statistics. Online conversations can complement the statistical indicators, showing how

people perceive employment status and what coping strategies they apply during times of uncertainty.

United Nations Global Pulse Initiative and Big Data

The United Nations (UN) began in 1945 with the purpose of promoting world peace and promoting the well-being of all people by lessening hunger, disease, illiteracy, and human rights abuses, especially in developing nations. Over time, the overall mission has remained the same, but some of the methods for achieving those goals have changed. Recently, as the private sector has found value in using big data to understand its customers, the UN has also seen the value in big data. In 2009, the UN started the UN Global Pulse initiative. The initiative brings together international development experts with big data scientists and

open source experts to develop a means of using big data to better understand and more quickly respond to humanitarian needs caused by natural disasters, socioeconomic crises, and other incidents, especially in locations with the world's most vulnerable populations.

Global Pulse has been investigating the use of big data from a variety of data sources, including physical sensors, private sector sources, crowdsourced reports, and online sources. As for physical sensors, satellite imagery and traffic sensors can be used. Private sector data would be, for example, anonymized mobile phone data and search data. Citizen-produced mobile phone surveys are an example of crowdsourced data. Online sources consist of online news stories, obituaries, birth announcements, job announcements, and social media posts on blogs, Facebook, and Twitter.

Tools

A variety of public-domain, open source, big-data tools already exist to gather and analyze the data coming from a variety of sources. Global Pulse has aggregated the tools into the Global Pulse Toolset to assist its mission. The toolset allows users to gather, analyze, and visualize big data related to their development projects.

One specific set of tools that Global Pulse continues to develop is HunchWorks. HunchWorks allows researchers and in-the-field development workers to view possible trends in big data, confer with peers, and then act upon the data. The user and their peers will be able to communicate via social media, share data via data repositories, analyze the data with available online toolsets, and then share data and recommendations with policy and decision makers, all in a relatively short period of time. With HunchWorks and the other Global Pulse tools, the idea is to be able to react before a crisis (such as economic or natural) causes too many ill effects.

Pulse Labs

Along with its headquarters in New York, Global Pulse has begun establishing hubs or Pulse Labs in other world cities. At the Pulse Labs, local experts and government officials work with Global Pulse to develop local big data projects that serve a local humanitarian need. The first

Pulse Lab, launched in 2012, is in Jakarta, Indonesia. Using social media data, mobile phone data, geospatial mapping, and other forms of data, the Jakarta Lab focuses on issues of food and fuel prices, unemployment, and poverty. Indonesia is an ideal location for the first Pulse Lab because it is a developing nation, but it is also an informationalized nation. According to Global Pulse, Indonesia has a large percentage of mobile phone users, and the people of Indonesia post 1.5 million tweets per day.

Other Projects

Global Pulse teamed with Crimson Hexagon, a social media analytics company, for a specific project that gathered and analyzed Twitter data to help better understand citizens' concerns about food and fuel costs and concerns about finances and housing. The project researchers found that, for example, in Indonesia, the number of tweets about the price of rice correlated with official food-price inflation statistics. In the United States researchers found, for example, that finance-related tweets increased during the U.S. debt ceiling debate in summer 2011. The researchers concluded that while Twitter data have limitations, they can be helpful in gauging a population's financial concerns.

In another project, Global Pulse used social media data to study citizens' moods related to unemployment in Ireland and the United States. Working with SAS, a business analytics company, Global Pulse used SAS analytical tools to determine the mood of social media posts. Based on the wording of the posts, each post was categorized as depressed, hostile, or confused. Researchers found that posts categorized as "confused" spiked three months before unemployment spiked in Ireland. Thus, the spikes in the confused mood serve as a predictor of unemployment spikes. In the United States, the researchers found that social media posts about the loss of housing increased two months after unemployment spikes. Such findings could help U.S. policymakers identify and deal with the more important consequences of unemployment.

Ethical Concerns

The use of big data by Global Pulse can provide helpful and actionable information. However,

ethical concerns arise with the use of big data and individual privacy rights. Global Pulse addresses this concern by anonymizing the data (i.e., stripping the data of individual names and other identifying data). Global Pulse states that they are not monitoring individuals; instead, they work with large, aggregated, and anonymized datasets at the regional or national level. This may raise issues of national sovereignty, but if Global Pulse is collaborating with government officials, then this concern is lessened.

Conclusion

In the past few years, Global Pulse has organized experts, developed or aggregated needed big data tools, established Pulse Labs in other world cities, and has conducted over a dozen big-data humanitarian projects.

In the future, Global Pulse plans to continue establishing Pulse Labs around the world. It also plans to continue developing partnerships with businesses in order to access sales data, mobile phone data, and search data. This sharing of anonymized data by businesses is what Global Pulse calls “data philanthropy.” In the next few years, Global Pulse will also continue sharing its big-data toolkits and its expertise with others interested in using big data to help in humanitarian efforts around the world.

United States

Social media have transformed almost every facet of life in the United States. Social media are often referred to as “new media” or “alternative media.” This terminology contrasts with the term *old media*, which means traditional media sources like television, newspapers, and radio. Social media utilize the tools and technology of the Internet, and are designed to be interactive, collaborative, and open spaces on the Internet. Examples of social media include, but are not limited to Facebook, Twitter, Myspace, Tumblr, YouTube, LinkedIn, Flickr, various social networking sites, blogs, Web forums, and wikis.

Social media can be used for professional and personal purposes. LinkedIn is a professional association networking site for adults, and Instagram facilitates the sharing of pictures and other images. Everything from institutions like education and business to civil society, politics, journalism, relationships, new forms of protest, and even how public opinion is constructed and disseminated has been impacted by the development of virtual communities that are largely free from the constraints of time and distance. Online communities like Facebook allow sharing of information, ideas, and opinions.

Occasionally, these networks focus on topics and stories that the traditional media has not highlighted or has discontinued discussing. Televised news channels may report a popular story that first made its way through the blogosphere, thereby increasing the visibility and credibility of social media sources. Or, the process may work the other way around, with social media focusing on topics initially covered by traditional media outlets. Social media communities weighed in on the 2012 presidential election in the United States, even prior to the official announcement on mainstream media. Newspapers reported their opinions.

Social media’s relationship to traditional media and other technologies is complex, with a gradual pace toward integration. Yet, social media is more than a tool for marketers, politicians, protesters, and organizations. How people live their everyday lives has been impacted, both positively and negatively. Concerns for privacy, abuse, and censorship have been reported. Communicating

in a wireless world has been revolutionized, as well as how Americans work, play, and understand the world. Sociologists are researching the impact of the new media on class, race, ethnicity, gender, and other facets of human diversity. Recognizing that an increasing number of users are female and minorities, feminists argue that even childrearing has not been spared from the tentacles of social media. Social media have changed the way Americans interact with the rest of the world, communicate and share information, and live the American dream.

Social Media and Relationships

According to users, what social media do best is redefine and sustain social relationships among people. A 2011 survey conducted by the Pew Internet and American Life Project found that communicating and maintaining social ties with friends and family were the primary reasons that many adults used social media. Younger users also enjoyed staying in touch, but used social media more broadly for sampling music, following their favorites, and tweeting. The transformative aspects of social media may not be the technology, but what these interactive technologies can enable and enhance.

In the social media sphere, Facebook rules the roost with more female than males using one of the most popular social media technologies created, according to the Pew Internet and American Life Project. The sexes are equally divided in the use of other social media technologies, but young people between the ages of 16 and 29 still dominate the social media scene, although by a somewhat shrinking margin.

What do users do on Facebook and other social media sites that create value in developing new relationships and sustaining old ones? Users can create or share content in the form of pictures and videos of themselves and family and friends, or share Web sites and other information found on the Web. The Pew Internet and American Life Project found that most adult users (46 percent) created and shared content in the form of videos and photographs, rather than relying on Web-created material. These individuals are referred to as “creators.” “Curators” are individuals who select to repost or retweet information or images from already existing Web sites. Approximately

32 percent of social media users are both creators and curators. They create content and repost existing content while reconnecting with family and friends.

The rise of social media is correlated with the development of other supportive technologies that enhance the capabilities of social media. For example, the creation of content is enhanced by smart technologies, such as the smartphone. These multifaceted and multifunctional mobile phones have built-in cameras and video capability. These smartphone technologies are relatively easy to use, and make sharing and creating digital content easier than sharing data or content between multiple devices and mediums, such as cameras and computers. The evidence is in the use. In a 2012 survey of 3,014 adults, the Pew Research Center’s Internet and American Life Project discovered that smart technology is popular among 18- to 29-year-olds who own 66 percent of smartphones. In 2012, nearly half of adults in the United States owned a smartphone. This enabled them to have ready access to social media applications through their phone. Taking pictures and sharing them was found to be one of the most popular activities for smartphone users.

A high level of engagement with social media, either as a creator or curator, is translated into having a high level of social currency or online social status and presence. Not all social media use is related to social engagement or consumerism. During the recession, social media users networked with others as a way of relaxing and relieving stress brought on by a bad economy, according to a 2009 Pew Research Center’s Internet and American Life Project report.

Social Media and Protest

Social media are powerful instruments for social change. The events surrounding the Arab Spring are often cited as an example of how these virtual communities can coalesce around causes that lead to action. Social networkers in the United States have pooled their collective voices to protest policies, practices, and power arrangements. These seemingly leaderless forms of unrest played a role in the Occupy Wall Street Movement that called for an end to the unsavory practices of Wall Street and the Trayvon Martin case, among other cases not mentioned here.

Displaying the #IAmTrayvonMartin Twitter hashtag on a t-shirt at a "Justice for Trayvon Martin" rally in Oakland, California, on July 20, 2013, after the announcement of a Florida court's not guilty verdict for Martin's killer, George Zimmerman. The Trayvon Martin case and resulting protests were widely discussed on social media networks, drawing a high level of awareness to the case.

There are many more subtle ways in which social media lend themselves to protest and social change in the United States. Comparing the old media (radio and television) with new media (social media, such as Facebook and Twitter) is a means of comparing a more familiar revolution with ongoing or emerging ones. Comparing the relationship between the old media and unrest is instructive in better understanding the role of social media and protest today.

Television coverage of the civil rights movement contributed to the demise of legally sanctioned segregation in the United States. In similar ways, continual social media coverage of the Trayvon Martin case led to mounting social pressure on both sides to either bring a killer to justice or release an innocent man. Mark O'Mara, the criminal defense attorney for the accused, embraced social media to clear his client's name.

The accused created a Web site to raise funds for his defense. After the shooting, protesters used Facebook and Twitter to organize and stage protests throughout the United States to raise awareness of the killing of an unarmed young black man in 2012. Until the Martin case, social media were not typically used in criminal cases, and this development raised the visibility of how the medium might be used in the legal profession and law enforcement.

From the 1955 Montgomery bus boycotts to the 1964 Democratic National Convention in Atlantic City, old media such as radio and television brought the nonviolent civil disobedience campaign of the civil rights movement and the violent responses of law enforcement to a shocked audience of television viewers. Old media played a similar role to new media that broadcasted footage of Tahir Square in Egypt on YouTube and

Facebook, and of police arresting youth during the Occupy Wall Street movement that began in Zuccotti Park in the financial district of lower Manhattan and spread to cities across the United States. While the movement was criticized for an overemphasis on physical space due to the erection of physical camps, it also had a strong online presence with social media.

Protesters during the 1950s and 1960s did not have Facebook or Twitter to get their message out or as an organizing tool to rally the masses. What they did have was the gradual emergence of the television in American living rooms. First in black and white and then in color, the percentage of homes in the United States that had television almost doubled in the late 1950s and early 1960s. Television earned its place in the psyche during the civil rights movement in similar ways that online virtual networks and communities like Facebook and Twitter are earning their places in the practices of the legal community. The ascendancy of television, like the ascendancy of social media, is increasingly becoming the new mediator of public opinion.

The multidirectionality of the old and new media becomes more apparent over time as both sides in protest movements and social unrest use the old and new media in multiple ways for multiple purposes. When the printing press was invented, word of mouth was the old media, and newspapers were the new media. When television was invented, newspapers were the old media, and anchorman Walter Cronkite was the new media. The Internet and social media have augmented, not usurped, the role of traditional media.

Social Media and Business

Social media have changed the way business is conducted in the United States. Both producers and consumers, as well as those who broker sales and services between them have seen massive changes. Virtual online communities such as Craigslist and Angie's List are two online buying and selling communities that have rivaled traditional advertising venues for used and new goods. Other social media outlets support Craigslist and Angie's List by offering venues to not only communicate with friends and families, but also comment on the quality of the goods and services auctioned in these and other similar

outlets. Customers can tweet good deals—and bad ones too. They can gather and share information from Facebook friends before making major investments and purchases. Consumers can also conduct research on products and services with online advice from any number of professional communities.

Businesses interact with customers in ways that were not possible before social media. Previously, businesses might use the postal service or elevated billboards to reach customers. They might buy expensive advertisements in newspapers, trade magazines, and television to reach consumers in larger markets. Today, businesses and organizations leverage a variety of social media tools to reach customers, enhance marketing, and increase brand visibility. In 2012 the U.S. Department of Education launched a new Web site and several redesigned social media outlets such as Facebook, Twitter, and YouTube to facilitate additional venues for students to learn about financial aid options and college admissions.

Many companies have created special positions designed to interact with and oversee their social media infrastructure. Marketers in these positions focus on emotion and engagement as part of the overall customer experience. They hope to use social media to increase their Twitter following and enhance brand loyalty. Consumers are empowered with access to the social network, but also exposed to spam, fraudulent claims, and educational and literacy concerns.

Social Media and Literacy

How have social media impacted education and literacy in the United States? What does it mean to be a literate person in the 21st century with the proliferation of social networks? According to a 2010 Pew Research Center report, the number of teens in America using social networking Web sites such as Myspace, Facebook, and Twitter has increased from 55 percent in 2006 to 73 percent in 2010. Myspace was the most popular networking Web site reported among teens in the 2012 report. Twitter is the most popular among teenage girls of high school age. Almost all youth in this age group use e-mail, cell phones, and the Internet on a regular basis. Blogging, an activity that requires lengthier and more complete prose, has sharply decreased among teens and young

adults. However, the use of shortcut emoticons like smiley faces, such as “:-)” to communicate on social networking Web sites has increased due to software that requires brief responses.

Worried by this preoccupation with technology, James Billington, the librarian of Congress, expressed concerns about what he called the gradual deterioration of the sentence. Billington was referring to the increasing number of young people who composed their thoughts in disjointed prose suitable for small gadgets and short attention spans. Twitter only allows 140 characters for each message.

Social Media and Minorities

Some researchers and academics have argued that social media may have a negative impact on the academic performance of underserved minority youth in the United States. They ask how disenfranchised students who may already possess skill deficits in traditional reading and writing formats will be affected by technologies that could care less about diagramming a sentence or verb and subject agreement. Others ask if these skills are relevant in the age of spell check and editing software.

Many young people and their parents contend that these skills are not only relevant, but also need further emphasis, according to the National Commission on Writing. Furthermore, a 2008 Pew Research report found that parents and their children still value traditional reading, writing, and grammar, and believe it to be important to their success. However, the report also found that forms of visual rhetoric like shortcut text emoticons and acronyms like “LOL” (laugh out loud), “CYO” (see you online), and the ubiquitous smiley face that are normally reserved for chat rooms and online conversations had crept into teens’ school writing assignments, and even their speech.

African American and Hispanic teens reported greater usage of these shortcut icons in their speech and school writing assignments than their white counterparts, according to the National Commission on Writing. They also reported writing in journals and composing rap lyrics more often than their counterparts. While reading and writing scores for African Americans and Hispanics have risen in the last 10 years, according to

the National Assessment of Educational Progress (NAEP), stubborn gaps still persist.

In the wake of emergent social media technologies like Facebook, Twitter, and Tumblr, how might the literacy traditions of minority groups change, and what might these changes mean for them and the larger society? Minority or ethnic rhetorical literacy traditions can be challenged and delegitimized if more dominant traditions serve as the model to be emulated. Adam Banks’s discussion of the rhetorical traditions of African Americans and their technology access is helpful. Banks argues that addressing issues of social justice is an important rhetorical tradition of African Americans that impacts their access to technology as well as legitimizing how they use it. Whatever the culture, social media literacy is a dynamic concept. This means that social media literacy practices evolve with society.

Social Media Concerns

In addition to the unintended consequences of social media, other concerns have been raised. Some researchers of public interest and public policy have noted that social media’s ability to democratize or provide a public commons or square may be overstated. Social media’s capacity to remain free and unfettered of politics and the market remains uncertain, and many suggest that more regulation is needed. Regulatory concerns have been raised over intellectual property, copyright infringement, censorship, defamation, trademark and patent infringements, and invasion of privacy. A lawsuit resulted in 2003 when pictures of Barbra Streisand’s mansion were posted on a Web site. News of the celebrity lawsuit resulted in a spike of hits to the Web site, thwarting efforts to decrease or prevent viewing of the award-winning actress and singer’s private home before the material could be removed. This has been referred to as the Streisand effect. State and federal governments are finding it difficult to pass legislation in this rapidly changing environment.

Using a Creative Commons license is one way that social media outlets disseminate and share copyrighted materials in an ethical manner. There are several types of Creative Commons license. This license provides both user and creator with rights to the of the content protected under law.

These rights allow for sharing and modification of content, depending on the type of Creative Commons license.

Even with a flexible license on how social media content may be used, parents of children and teenagers who use social media have expressed concerns for safety and privacy. In addition to worrying about what their children are doing online, parents are also concerned with who their children are doing it with. A 2012 Pew Internet and American Life Project report found that 72 percent of surveyed parents of teenagers who use social media expressed concern about the nature of their children's behavior on social networking sites. However, their concerns did not end there. Parents also expressed concerns about the impact of online advertising, the divulging of confidential information, sexual predators, and how their child's online behavior might impact their reputation and future standing for college admissions and employment pursuits.

Several recommendations have been offered to parents, caretakers, and schools concerned about safeguarding their children's social media use. Recommendations included limiting their child's Internet time and regularly monitoring the digital footprint of their children. This can be done by participating in the social media sites that their children use. The U.S. federal government also enacted the Children's Online Privacy Protection Act of 1998 (COPPA). This act places restrictions on persons, organizations, or Web sites collecting sensitive information from children under the age of 13. The act also provides guidelines for seeking parental consent, and places restrictions on pandering and marketing to children under the age of 13. In response to COPPA, Facebook requires that users be over the age of 13 before they can participate on Facebook.

Social Media and Politics

Social media, with their ability to reach and influence millions of people in low-cost and efficient ways, have increasingly been used in political campaigns. The 2008 and 2012 Obama-Biden administration maintains a White House blog that discusses various events taking place in the United States. The blog is licensed under the Creative Commons Attribution 3.0 License, allowing

more flexibility in how the posted content can be shared or used.

Yet, social media is more widely known for how politicians have leveraged these tools to win elections, advance their agenda, and communicate with constituents. In a March 18, 2008, speech titled "A More Perfect Union," then presidential candidate Barack Obama discussed his views on race. According to the Pew Research Center, the speech received 2.5 million hits on YouTube within the first 72 hours of its delivery. It also generated 4,000 comments in the blogosphere. Obama's 2008 election team heavily utilized social media as a campaign and re-election strategy.

Political commentators and authors Chuck Todd and Sheldon Gawiser attributed the effective use of social media in reaching young voters as one strategy that the Obama campaign team used to win the 2008 presidential election. The 2012 presidential campaigns of President Obama and Governor Mitt Romney, and the 2008 campaign of Senator John McCain also used social media in their outreach efforts. Social commentators reflect on how social media is increasingly being used to reinforce existing political ideas, rather than exposing users to a variety of viewpoints.

Users of social networking sites such as Facebook and Twitter identified social networking sites as important places for their political and social activism in 2012, according to a report published by the Pew Research Center's Internet and American Life Project. About 36 percent of social networking users identified these sites as very or somewhat important to them in staying informed on political issues. Approximately 26 percent of users felt that social networking sites were important to them in finding and collaborating with politically likeminded people, according to the report. Still others identify these sites as relatively unimportant in their political life.

U.S. Pentagon Social Media in Strategic Communications Program

The U.S. Department of Defense has struggled to effectively monitor, implement, and counter the use of social media by both military personnel and organizations, and by terrorist groups. Following a relatively restrictive approach to social media, the Pentagon increasingly acknowledged the importance of social media technologies and the changing nature of contemporary warfare. To this end, in 2011, the Defense Advanced Research Projects Agency (DARPA) solicited grant proposals for its Social Media in Strategic Communications Program.

Social media technologies are a central component of contemporary military communications. They allow for command-and-control capabilities; improve public relations that connect the Armed Forces with the public, journalists, and other constituencies; and offer a form of recreation for military personnel. The Pentagon has had a complex and consistently changing view of, and approach to, the use of social media by soldiers and the military establishment. In May 2007, following a number of controversial videos posted to YouTube, the Pentagon officially restricted access to social media sites, citing concern over security and bandwidth.

That policy remained in place until February 2010, when Directive-Type Memorandum (DTM) 09-026 increased access under restrictive

conditions. DTM 09-026, called the "Responsible and Effective Use of Internet-based Capabilities," allowed for the use of social media by military personnel as long as they did not compromise operational security or access prohibited content. Commanders retained control over implementation of the policy, allowing for restrictions meant to preserve cybersecurity and/or mission readiness at the local level. As noted by Deputy Secretary of Defense William J. Lynn, the directive tried to achieve a balance between security and the benefits provided through "21st-century Internet tools." DTM 09-026 remained in place until August 2012, when it was amended to address the use of .mil e-mail addresses. In particular, a hack of a military dating site raised concerns about network security. Thus, the Pentagon requested that military personnel not use their official e-mail address in accessing commercial social media sites.

Within this fluid new media environment, Pentagon officials increasingly recognized that hostile groups were using social media for spreading misinformation and rumors that were detrimental to military and humanitarian missions. Daniel Bernardi and his colleagues at the Consortium for Strategic Communication at Arizona State University provide several examples of rumors initiated and spread by both insurgent groups and the U.S. military in Iraq, Indonesia, and Singapore in their book. These scholars suggest that rumors are like "narrative IEDs (improvised explosive devices)" that are locally constructed (and therefore highly symbolically potent), but are difficult to detect. More importantly, rumors are transmediated across multiple platforms—from face-to-face communication, to online message boards and social networking sites.

Strategic Social Media

Thus, the Defense Department began to explore strategic uses of social media. It had always used social media to provide information on military affairs, including a YouTube site dedicated to engagement in Iraq (MNF-Iraq), the use of Twitter for updating policies and procedures, and the use of video games for training and recruitment. However, the focus began to shift to uses of social media beyond public relations and information dissemination. The Pentagon's "Perception Manager,"

John Rendon, had at one point emphasized the Defense Department's effort to devise, implement, and manipulate Internet algorithms meant to help track and shape "belief sets."

Soon thereafter, the Pentagon's Social Media in Strategic Communications Program (SMISC) was revealed in July 2011. Sponsored and facilitated by the Defense Advanced Research Projects Agency (DARPA), it involved a call for sponsored research projects of \$42 million over three years, and was intended to develop the use of social media tools more strategically in cyberwarfare and information-security endeavors. The program will focus on areas where troops are deployed, with an emphasis on quickly identifying and dispelling dangerous rumors or persuasive campaigns. The call addressed the creation and testing of algorithms and other applicable experiments such as massively multi-player online role playing games (MMORPGs).

Grant Solicitation

In the grant solicitation announcement, DARPA recognized the proliferation of social media and social networking sites, as well as the growing use of mobile devices and associated applications. The solicitation narrative also recognized that military operations and the "nature of conflict" more generally were rapidly changing in a digital media environment. Moreover, the solicitation acknowledged that the military must more strategically and methodically use social media. In particular, the military intended to privilege projects involving three areas: (1) the detection and tracking of misinformation and/or memes, (2) the identification of persuasive campaigns and their originators, and (3) the crafting of counterpersuasive messages.

The grant solicitation provided an example of a detrimental rumor that took place in a current war zone. Military officials happened to be monitoring social media, and were able to dispel the rumor before it compromised operational security. However, the incident highlighted that such methods and tools were currently "dependent on chance." Thus, new efforts must be developed that overcome a "reliance on luck" through systematized and/or automatic approaches.

In the grant solicitation, DARPA further stated that the program was meant to identify and track

ideas and other risks spreading via online communities. Concurrently, the Pentagon planned to use such online communities to launch counterinformation campaigns against groups like the Taliban. Such proactive responses helped to control rumors that functioned to prevent mission and/or humanitarian success.

According to the DARPA Web site, the program was meant to "prevent strategic surprise." DARPA officials noted that the goal was to develop a "new science" of social media technologies and networks, including tools meant to support "efforts of human operators" working to detect and counter deception and rumor campaigns by terrorists or other insurgent groups. Such efforts would focus on "linguistic cues," information and opinion generation and flow, notable memes, or cultural narratives. Successful research endeavors would allow military personnel to model and analyze both online communities and content, with the ultimate goal of launching timely and effective counterpersuasion.

DARPA also sought proposals to create an environment in which "controlled experiments" using big datasets could be explored and engaged by researchers seeking to test developmental software and/or tools. The organization noted that such environments could take the form of MMORPGs or "closed social media networks" of people who willingly participate in data acquisition and analysis procedures. The SMISC program identified four specific approaches: (1) detect, classify, measure and track the formation, development and spread of ideas and concepts/memes, as well as purposeful or deceptive messaging and misinformation; (2) recognize persuasive campaign structures in order to influence various operations across social media sites and online communities; (3) identify concept/campaign originators and their intent, and measuring the impact of a specific persuasive campaign; and (4) craft and disseminate counter messaging and/or campaigns.

Thus, the SMISC research program involved cluster areas around linguistic and narrative mining and analysis, meme detection, community modeling, and content generation. Specifically, three technical areas were identified in the grant solicitation. First, the algorithm and software development area sought proposals for the tracking of misinformation spread via online

A U.S. Army public affairs officer works with an enlisted soldier to add photos and news about a field exercise to a heavy combat brigade's blog in Korea in 2009. By February 2010, Directive-Type Memorandum 09-026, called the "Responsible and Effective Use of Internet-Based Capabilities" memorandum, allowed military personnel to use an increasing amount of social media with certain restrictions and under the control of their commanders at the local level.

sites and communities. This would allow the military to provide counterpersuasion to such campaigns. Second, the data provision and management area sought proposals for experiments on large amounts of data, with the ultimate goal of testing software developed in Technical Area 1. One such method involved the creation of MMORPGs to test the aforementioned tools. Third, the algorithm integration, test, and evaluation area sought proposals that would develop metrics for assessing the performance of tools and software.

Winners of the grant funding included the Center for Complex Networks and Systems at the University of Indiana, in partnership with the University of Michigan, who were awarded \$2 million for their proposal "Detecting Early Signatures of Persuasion in Information Cascades";

the Information Sciences Institute at the University of Southern California, which was awarded \$6 million for their study "Situational Awareness for Social Media: Theories, Models, and Algorithms"; and the University of California Riverside, in collaboration with Rutgers University and IBM for their proposal "Understanding and Utilizing Context-Aware Information Dissemination in Social Media." Overall, such programs will contribute to a more strategic, intentional, and successful use of social media by the U.S. Pentagon.

USAID Impact Blog

The USAID Impact blog is a social media initiative of the U.S. Agency for International Development (USAID). The Web site is hosted and maintained by the U.S. government. As described and detailed on the blog, its main purpose is to create and share stories related to the success, failure, and evolving progress of individuals who are employed by and often conduct field work for USAID.

The blog is specifically designed to create, frame, disseminate, and detail the role of USAID in helping the world's poor through narrative and visual storytelling. The blog's aim to act as a means of U.S. diplomacy, domestic and foreign, also emerges as a prominent and salient purpose of using this medium of communication. According to USAID's overarching mission shared on the main Web site:

The U.S. has a long history of working with individuals around the world that, among other things, are living in poverty, lack food security, do not have access to clean water, and struggle to prosper.

Providing aid to these individuals and communities by USAID reflects U.S. citizens' compassion

and support of human dignity. USAID's Web site also acknowledges that aid in part advances U.S. foreign policy interests. However, as some scholars have noted, the furthering of policy interests and stakes by providing potentially lifesaving food, water, medicine, and related supplies in exchange for U.S. political gain and/or to protect national interests has been critiqued by development scholars and foreign governments alike for its potential for creating an unequal and imbalanced power relationship between the United States and the people and governments of developing countries.

In 1961, under John F. Kennedy's administration, USAID was created in part as a response to a consensus formed at the highest levels of the U.S. government that international development is integral to the shared and mutually beneficial interests of an interconnected planet. In 2013, spending less than 1 percent of the total federal budget, USAID worked to provide aid to over 100 countries worldwide. This aid is particularly important given that over 1 billion people live in poverty, and threats posed by climate change are mounting. USAID also carries out U.S. foreign policy, which is highly value laden, by promoting stable and free societies, creating markets and trade partners for the United States, and fostering good will abroad via activities related to economic prosperity, strengthening democracy, protecting human rights, improving global health, working toward food security, furthering education, and helping societies prevent and resolve conflicts.

The USAID Impact blog is designed to further the development of good will created around the work that is undertaken and completed in the developing world by USAID. Recent examples from the blog's homepage of issues covered include "What I Saw and Learned in Southeast Asia and Why I Left Inspired" by Chelsea Clinton (former President Bill Clinton's daughter), "MCHIP's Respectful Maternity Care Toolkit Promotes Positive Attitudes in the Care of Women and Newborns," "Proof That the U.S. Government, NGOs and Activists are Working Together on Nutrition," and the caption from the most recent "Photo of the Week" was "Nutrient-Rich Crops for Kenyan Children." The headlines generally appear to convey messages related to

underlying U.S. values, optimistic development progress, and encouraging outcomes—and all suggest a win-win approach to this form of international development and foreign policy.

It is unclear who specifically moderates the blog and/or who is the central party that oversees content and blog comment moderation, though it may be assumed that an employee in the Information Center (its contact information is listed on site) at USAID may direct it. The blog has a general disclaimer that states that the blog provides external links for the sole purpose of the readers' information and convenience. It further states that when readers select a link to an external Web site, they are leaving the usaid.gov site and are therefore subject to the security and privacy policies of the external Web site.

The homepage of the blog has social media links to Facebook, YouTube, Flickr, LinkedIn, and Twitter accounts, and an really simple syndication (RSS) feed page that when clicked on further state this disclaimer and make the reader aware that the content on these pages is not sponsored by the U.S. government or USAID. These links also help support ways in which the U.S. government has begun to understand the role of social media tools as providing important platforms for message framing, content disbursement, and online diplomacy action.

The blog also has a comment policy that states that it is a moderated blog, which means all comments will be reviewed before posting, which allows USAID to maintain some control over how their content is understood and interpreted. In addition, the policy puts forth an expectation that blog participants will treat each other, as well as the USAID Agency and their employees, with respect. They state that they will not post comments that contain abusive or vulgar language; offensive terms that target specific racial or ethnic groups; or personal attacks of any kind.

It is also made clear that all references to other nongovernmental organizations (NGOs), products, services, or individuals that remain on the site are not intended to reflect the opinion of USAID, the United States, or its officers, and do not represent the significance, priority, or importance to be given the referenced entity. Finally, the blog states that its use policy is subject to amendment or modification at any time to ensure that it

is consistently used with its intended purpose as “a limited forum.”

Conclusion

USAID Impact blog is a reflection of the U.S. government's growing understanding that diplomacy, especially involving international aid and foreign policy, must continue to be created, framed, and moderated in a social media era, where information and images are often able to be mass produced and disseminated by anyone.

User-Generated Content

Over the past decade, new media technologies have allowed the general public to produce, publish, and disseminate content through increasingly interconnected Web services.

The term *user-generated content* refers generally to content that is produced and disseminated by unpaid nonprofessionals. Although there is no formal definition of user-generated content, the Organisation for Economic Co-operation and Development has written that user-generated content is creatively produced by active Web contributors, independent of journalistic practices and professional routines.

Types

User-generated content comes in a number of forms (e.g., text, video, audio, and mobile phone photography) and is disseminated through a variety of channels, including blogs, wikis, podcasts, news sites, social networking sites, customer review sites, and comment and discussion boards.

Despite their many forms, platforms for user-generated content are generally asynchronous and emphasize content and context over appearance and chronology. For instance, Facebook and Twitter users create personal profiles and share information on their own and each other's profiles, Flickr users document events by uploading and sharing photos with family and friends, and YouTube users freely upload, share, and provide commentary on videos, from a two-minute borough council speech recorded on a camera phone to a 150-minute self-produced documentary on the two-party system in American politics.

Growth

Before user-generated content became mainstream in the mid-2000s, political communication was primarily disseminated through professionally sponsored or journalistic outlets. These sites differ from traditional modes of dissemination in a number of important ways. First, they are easy to use and require little training. Second, they minimize the costs of and barriers to marketplace participation. Third, there are no space limitations on wikis and collaborative project sites. Fourth, as communication technologies such as digital cameras, digital video recorders, and smartphones have become more widely available and affordable to a larger percentage of the population, the number of American households with Internet access and broadband capability has exponentially grown in the past decade.

Recognizing these factors, many traditional media outlets have implemented interactive user-generated platforms, such as CNN's iReport, which often feature untrained, unpaid social media users and young people born after the advent of widespread digital technology ("digital natives") who are (1) more willing to share personal information and (2) prefer the colloquial and easily digestible information for which these platforms are known.

User-Generated Content and Politics

For many politicians and political campaigns, user-generated content is a cost-effective way to engage voters at the grassroots level. By encouraging citizens to contribute content, campaigns develop agendas and use the feedback to strategize more costly traditional techniques. Also, for many campaigns, the possibility of information "going viral," or multiplying quickly across many interconnected platforms, outweighs the unpredictability and questionable credibility of much user-generated content.

One of the highest profile examples of the influence of user-generated content occurred in the Arab Spring of late 2010 and 2011, in which widespread protests led to the overthrow of the ruling powers of several Middle Eastern and north African nations. Social networks such as Facebook and Twitter were used to announce protests and facilitate communication among protesters and the outside world. Content sharing of user-generated content became a source for news about and perspectives of the uprisings that were underreported by the mainstream media.

The reach of user-generated content is also felt in American politics. As a presidential candidate in 2008, Barack Obama used social media and user-generated content to an unprecedented extent, and according to YouTube Politics, only 5 percent of videos uploaded to YouTube about 2012 American presidential candidates Mitt Romney and Barack Obama were from official media sources. The remaining 95 percent were user generated.

Ushahidi

Ushahidi is a Web site and software company that promotes social accountability via information gathering and interactive mapping. Named for the Swahili word for "witness" or "testimony," Ushahidi was developed in 2007 following Kenya's disputed presidential election. The Web site was first used to map incidents of violence as the Kenyan crisis unfolded. Ushahidi has since resulted in several additional products, and has been used around the world by social activists and citizen journalists.

Origins

Ushahidi was first proposed by Ory Okolloh, a Kenyan activist, lawyer, and blogger who had prior experience in the field of digital activism. In 2006, Okolloh cofounded the parliamentary watchdog site Mzalendo. Swahili for "patriot," Mzalendo systematically recorded bills and speeches in order to increase government accountability. The following year, violence erupted in Kenya following a disputed presidential election between incumbent President Mwai Kibaki and his opponent Raila Odinga. Odinga supporters alleged electoral manipulation, resulting in a political, economic, and humanitarian crisis throughout the country.

In response to the Kenyan crisis, Okolloh worked alongside three other Kenyan residents—Erik Hersman, Juliana Rotich, and David

Kobia—to combine crowdsourcing with social activism. The result has since been coined "activist mapping": the ability for local citizens to create an interactive map or geospace by submitting firsthand reports and observations via their mobile devices.

The Kenyan crisis lasted a total of two months. During this time, Ushahidi was used to report and chart acts of violence throughout the country. Kenyan journalists and international media verified eyewitness testimony generated by Ushahidi. A subsequent study by the Kennedy School of Government determined that Ushahidi offered more comprehensive reporting than Kenya's mainstream media. Ushahidi was also found to be more reliable at reporting rural information and nonfatal violence.

Products

Following its initial use in Kenya, Ushahidi has since been developed as an open source platform, resulting in a variety of additional products. One such product, SwiftRiver, is a collection of data-gathering products that complement Ushahidi's interactive mapping technology. The goal of SwiftRiver is to help people make sense of a large amount of information in a brief period of time. SwiftRiver does so by structuring data, filtering and prioritizing content, and adding spatial context to information.

A second product that has resulted from Ushahidi is Crowdmap. As an activist alternative to sites like Facebook and Foursquare, Crowdmap allows people to "check in with a purpose." Through Crowdmap, users can quickly indicate their location and add more detail about their check-in later. Following Ushahidi's success, cofounder Okolloh accepted a position as manager of policy for Africa at Google.

Use

In more recent years, Ushahidi has been utilized around the world to record acts of violence, upheaval, organized resistance, and even natural disasters. In 2008, Ushahidi tracked anti-immigration violence in South Africa that left 62 people dead. In 2009, Ushahidi chronicled pharmaceutical stockouts in East Africa, political elections in India and Mexico, and the Gaza war between Israel and Palestinian militants.

A smartphone app developed in Nairobi, Kenya, in 2008 for Ushahidi. It allows mobile phone users to view and report incidents directly from their phones, generating interactive maps.

In 2010, Ushahidi traced earthquakes in Haiti and Chile, as well as winter storms in Washington, D.C., and wildfires in Russia. Measuring 7.0 on the moment magnitude scale (MMS), the Haiti earthquake marked one of the first joint efforts made by Ushahidi. In cooperation with the Fletcher School of Law and Diplomacy at Tufts University, the United Nations Office for the Coordination of Humanitarian Affairs, and the International Network of Crisis Mappers, the Ushahidi Haiti Project received nearly 40,000 eyewitness reports immediately following the 2010 Haiti earthquake. During Washington, D.C.'s, winter storms, Ushahidi was used to map road outages; during Russia's wildfire season, the technology was used to create a "map of help" for volunteer workers.

Finally, Ushahidi was used in 2011 throughout India, Japan, Libya, Australia, Macedonia, New Zealand, the United States, and the Middle East, among others. In New Zealand, Ushahidi

used the #eqnz hashtag to indicate locations for food, water, toilets, fuel, ATMs, and medical care. In the Middle East, Ushahidi was used by prodemocracy demonstrators to communicate ground conditions.

Conclusion

Ushahidi was developed as an interactive Web site to map incidents of violence following Kenya's 2007 presidential election. Swahili for "witness" or "testimony," Ushahidi uses information gathering and interactive mapping to promote citizen journalism, digital activism, and social accountability. Since its initial development, Ushahidi has resulted in a variety of products, such as Swift-River and Crowdmap; it has been used around the world by "activist mappers" who submit their firsthand reports and observations via mobile devices.

V

Value

Value is a generic term that may refer to a personal or cultural level, and may be used in domains such as ethics, sociology, and economics. In the context of social media and digital communication, however, it is interesting to think of values in terms of exchange and sharing. In other words, what values do people attach to the digital objects that they share via social mediating technologies? This question becomes increasingly pertinent with the potential convergence of producers and consumers that becomes possible with the dispersal of media technologies.

In an attempt to outline a typology of values, one may start with the notions of exchange value and use value. Exchange value, an idea used in both Marxist political theory and mainstream anthropology, refers to the value of a media object in terms of what it can be exchanged for (in monetary or trading equivalents). While the notion of exchange value could be dismissed in relation to the online sharing of digital media objects—on the basis that digital media objects are often not paid for—it can be argued that exchange value is still relevant in “microeconomic” terms in, for example, digital music stores and subscription services such as iTunes or Spotify. Also, the fact that digital media objects may not always be exchanged for money, but traded for other digital media objects

in various types of peer-to-peer networks, also signifies the viability of exchange value as an analytical concept. Use value refers to the practical utility an object has to a person (i.e., what it can/will be used for). This may of course vary depending on what type of media object is transferred (e.g., a music file, program, or text document), but can still shed light on intentions and specific uses of digital media.

However, the sharing of media objects in social networking services is not always as immediate or contractual as use or exchange values imply. As shown in market research, consumer studies, and design studies, other values, often more interpersonal, convivial, or collective, come to play an important part in these contexts. Studies of sharing in “noncomputerized” social contexts (e.g., reciprocal or altruistic gift giving) emphasize a different type of value that people attach to objects, namely social bonding value. Social bonding value, which is often referred to as the most important value in gift-giving research, is concerned with the social ties between people and how these are managed and maintained through the exchange of goods and services. A question that has so far received fairly little academic attention is how these values differ when the shared object is a digital media object, and the context is a computer-mediated, semipublic social network. However, a growing body of research

is addressing social bonding values as important parts of mediated sharing.

There are also additional “soft” values to be discussed in relation to social media. Research in interaction design, economic anthropology, and sociology, has come to emphasize ethical and aesthetical values. An ethical value relates to the risks and responsibilities that a user may perceive when using or sharing a particular media object. It could relate to, for example, social justice, truth, democracy, or principles of equality. The aesthetical value relates to a sensory and immediate experience. Ideally, the aesthetical value is connected to an affective experience that brings about a sensation of beauty, fulfillment, and purpose.

By conceptualizing value as something that can be attached to media *objects*, new lines of inquiry are opened up. However, this is in no way saying that objects dictate the surrounding practices or values, or that media objects are blessed with a certain essence. Rather, the examination of them as central objects can help explore the *relation* between specific media objects and the surrounding values and practices. By including not only exchange and use values, but also the more soft values that people ascribe to media objects, one may further the analysis of media objects as “technology-mediated cultural containers.” Accordingly, a careful consideration of such cultural containers has strong potential to shed light on issues and practices of social meaning.

In summary, value is an important concept in the critical study of technology, and social media in particular. Value is produced and negotiated in the intersection between producers and consumers, and is expressed in the way digital media objects are transferred and shared, for example. While the bulk of research has focused on use and exchange value, there are cross-disciplinary influences that have more recently emphasized the importance of social bonding, ethical, and aesthetic values.

Video Privacy Protection Act

The Video Privacy Protection Act (VPPA) protects against the collection and disclosure of information regarding an individual’s records of video cassette rentals (it was later interpreted that the law included protection of DVD, video game, and on-demand video rentals). The U.S. Congress passed the law in 1988 in response to the congressional hearings for U.S. Supreme Court nominee Robert Bork. During the nomination process, a list of Bork’s video rentals was published in a Washington, D.C., newspaper. Members of Congress were concerned about their records becoming public, and quickly passed legislation that made such information private. The leaking of such information can lead to both civil and criminal liability, including punishment of up to \$2,500. There are several exceptions to the law. For example, an individual can consent in writing to the release of rental records. Companies can also access information about genre preferences to use in marketing efforts. Police can also access records with a valid warrant. Theoretically, the government’s investigatory powers under the USA PATRIOT Act would allow it to circumvent the VPPA in cases of national security.

Some critics argue that the VPPA was a hasty, ill-advised overreaction to the Bork incident. Critics claim that in the process, the U.S. Congress singled out one industry without considering the consequences. For example, the records

of video purchases or rentals from public libraries were not protected. Such critics argue that the government reacts impulsively whenever there are such newsworthy controversies, and warn that the freewheeling Internet could suffer the same ill fate if users are not careful with rights to privacy and other civil liberties.

With the advent of social media and data-mining, new lawsuits have arisen under the once dormant VPPA. Judicial interpretations of the VPPA found it to be technologically neutral. This had prevented m-commerce providers from publically displaying an individuals' rental record online. As a result, several video streaming services and social media sites have been sued for violating the law. In 2008, a suit was filed against Blockbuster when it released rental records to Facebook. In 2012, Hulu also faced a class action lawsuit for violating the VPPA when it displayed rental records on similar social media sites.

In 2009, a suit was filed against Netflix after it released information through its Netflix Prize program. The costly lawsuits (\$9 million in damages), in addition to its inability to use social media marketing, led to Netflix suffering a 14 percent decrease in net profits for the fourth quarter of 2011. As a result, Netflix started a campaign to get its customers to contact their congressional representatives about amending the VPPA. Netflix argued that people should be able to know what other social media users are renting and what they recommend, as is allowed in Canada and Latin America. Furthermore, this prohibition on sharing records was not equitable because music services, such as Spotify, could share records. In response, U.S. Representative Robert Goodlatte (R-VA) introduced a bill to amend the VPPA to allow for rental records to be released if any consent is given by a consumer, not a written consent that was needed under the original law. If the law was amended, then companies such as Netflix could share information whenever a consumer watches a movie, whereas currently, the onus is upon the customer to share the information. The new law would have made the rental of a movie on Netflix the equivalent of a "like" on Facebook. Critics of the bill argued that large corporations would abuse the law by hiding consent in the terms of agreement, thus customers would unwittingly give up their rights to privacy.

In 2012, the U.S. House of Representatives drew up a new bill, H.R. 6671, and it passed both the House and U.S. Senate. It was signed into law by President Obama in January 2013. The new bill allows for video providers to gather consent through the Internet, and the consent is valid for up to two years (unless the consumer withdraws). Also, the consent must be conspicuous and cannot be hidden in the fine print of terms of agreement. Senator Paul Simon's words during the original hearings on the VPPA in 1988 echo the concerns still apparent today:

There is no denying that the computer age has revolutionized our world. . . . Yet, as we continue to move ahead, we must protect time honored values that are so central to this society, particularly our right to privacy. . . . Every day Americans are forced to provide to businesses and others personal information without having any control over where that information goes. These records are a window into our loves, likes, and dislikes.

The new law is a response to ever-changing technology and privacy concerns. Laws regulating access to online information were slow to develop, and a disparate assortment of laws is now on the books. Unfortunately, many of them have been made outdated and ineffective by changing technologies. The question still remains as to what information should be made available to the public on social media, and correspondingly, what information government authorities should have access to without a person's knowledge or consent.

Viral Marketing

Viral marketing refers to the application of traditional word-of-mouth marketing to the online environment. Originally developed by Steve Jurvetson and Tim Draper in 1997, the term is used to describe online techniques designed to generate peer-to-peer conversation and buzz about a company, brand, product, or service. A message that contains something of value or appeal is diffused throughout members of a given social network, and ideally across networks, in an exponential fashion, much like the spread of a virus in medical parlance. The rapid adoption of digital and social media tools by politicians has led to an increased visibility and impact of viral marketing efforts in political campaigns, particularly since the 2008 U.S. presidential campaign. Common viral marketing techniques include, but are not limited to, a systematic and strategic deployment of viral e-mail messages, YouTube videos, blogs, microblogs (such as Twitter), social networking Web sites, podcasts, online games, and text messages.

While word-of-mouth marketing, broadly defined as the sharing of information about a product between a consumer and members of their social network, has been an important topic of research for several decades, the interest and application of viral marketing rapidly grew in recent years with the emergence of Web 2.0, social media, and the diffusion of mobile or handheld devices. These technological evolutions not only fostered a consumer culture that encourages peer-to-peer sharing and participation, but more importantly, they created an online environment that allows individuals to transcend any geographic and time constraints to interact and maintain relationships with friends, family members, or other members of their social networks.

Viral marketing can be characterized as enhanced word-of-mouth communication that has several advantages. First, viral marketing has a much higher diffusion reach and speed. Traditional word-of-mouth marketing relies mostly on face-to-face communication with close friends, and is therefore limited by the size of a person's social network and physical boundaries. In contrast, viral marketing can instantly reach a much larger group of people, one can easily tap into his or her strong-tie and weak-tie social connections

with the push of a button on his or her computer or smartphone.

Second, success in viral marketing is easier to monitor. Whereas the spread of information or messages in traditional word-of-mouth is difficult to measure because interpersonal conversation leaves little to no tangible records, one of the biggest advantages of online marketing is its tracking ability. Digital transmission of information leaves a digital trail that can be documented by social media monitoring or search analytic services. Ultimately, the data collected during the viral diffusion process leads to better analysis and evaluation of a viral campaign on tangible communication (such as awareness and attitude change) or business (such as sales and referrals) outcomes.

Finally, viral marketing creates added value for the brand or product. While traditional word-of-mouth marketing generates conversation about a brand or product, a person's engagement with the brand or product may come to a stop once the face-to-face communication ends. The nonlinear nature of the Web and the interactive capability of social media that viral marketing relies on can create opportunities for brand engagement and consumer interaction well after the viral message is received. Further, because journalists and news organizations are increasingly turning to social media for information, viral marketing campaigns can also generate additional coverage and publicity in traditional mass media.

Characteristics and Advantages

A successful viral marketing campaign shares two important characteristics. First, the initial "seeding" of the virus must be done with the right people. Consistent with Elihu Katz and Paul Lazarsfeld's two-step flow theory of communication, ideas flow from a source (including brands, media, or celebrities) to opinion leaders, and from them to a wider population. In the context of viral marketing, the opinion leaders could be active media users who have strong professional expertise or reputation. Otherwise, they could also be individuals with a large number of social connections who also tend to act as connectors between different social groups. As opinion leaders exert influences on their networks to share the viral message, its dissemination is amplified and can exponentially grow.

The second critical factor lies in the viral message. In order to prompt the forwarding or sharing behavior, the message must present some value to the receiver. Such value could manifest in the forms of information, functionality, entertainment, or emotion. The classic example that Steve Jurvetson and Tim Draper cited in 1997 was the initial growth of Hotmail.com, which included free e-mail, account offers on all outgoing e-mail and thus spread the message within the sender's social network. More recent examples of viral marketing tend to contain humor, sexuality, violence, or interactive elements that are used to add a sense of value to the receiver.

When successfully done, viral marketing can provide a number of advantages to an organization. First, it incurs very little expense because peer-to-peer sharing is free. Therefore, viral marketing may significantly reduce or even eliminate

the need to buy media space for promotional purposes. Second, since viral messages come to individuals from their friends or family, they may be viewed as more credible than traditional marketing messages. Finally, individuals forwarding viral messages are more likely to know the interests and preferences of the recipients, thus making the targeting more effective and allowing the message to better break through the media clutter.

Use in Political Campaigns

There have been numerous instances where viral marketing messages or campaigns became an important part of the contemporary political process. The political use of viral marketing can be approached from three perspectives: (1) viral marketing efforts implemented by politicians, particularly during electoral campaigns; (2) viral marketing efforts implemented by civic organization

Posters promoting the viral video campaign Kony 2012 in Warsaw, Poland, in April 2012. This 30-minute documentary film was produced by Invisible Children, a nonprofit charity that sought to bring to light the activities of the Lord's Resistance Army (LRA) and its leader Joseph Kony in Uganda. It broke all viral viewing records with more than 100 million views in less than a week, and raised \$20 million.

or grassroots groups to advocate certain policies or causes; and (3) user-generated content that has “gone viral” with the implicit or explicit intent to influence politics.

One of the earliest examples of politicians tapping into the power of viral marketing was Howard Dean. In his bid for the Democratic presidential nomination during the 2004 presidential primary campaigns, Dean utilized Meetup.com to organize scores of passionate supporters, who went on to spread the word and recruit their friends and families to Dean’s campaign. The campaign gained momentum on the ground, and received more mainstream media coverage. Eventually, Dean failed to win the Democratic primary, but his campaign made political history. In subsequent political races, politicians adopted and improved upon various aspects of Dean’s Web strategy. For example, nearly every e-mail message that George W. Bush’s campaign sent out in 2004 provided recipients a way to forward the content to other people.

The second way that viral marketing efforts may influence politics is when they are used by civic organization or grassroots groups to advocate certain policies or causes. For instance, one of the most popular videos to go viral on the Web in recent years was the *Kony 2012* short film produced by Invisible Children, a nonprofit charity aimed at bringing awareness to the activities of the Lord’s Resistance Army and its leader Joseph Kony in Uganda. The 30-minute documentary incorporated elements of information, human interest, and emotional appeals. It took only six days from its initial release to reach 100 million viewers, making it the most viral video in history. Despite success on the Web, the organization failed to create much offline activity in its “Cover the Night” event, and the campaign got lost in the media clutter. Other examples in which viral marketing became an integral part of social movement or advocacy efforts include the Arab Spring and Occupy Movement; both took advantage of the reach and effectiveness of viral techniques in social media in their push for social change.

Finally, in contrast to the two scenarios described above where viral marketing messages are purposefully designed and distributed by an organization to achieve a strategic purpose, the last category can be attributed to the Web

2.0 culture of user-generated content and the incessant passion to “upload” and share everything. With the proliferation of camera phones and video recording and editing devices, many political spectacles on the campaign trail, such as speeches, rallies, or even television and radio interviews all become potential viral materials when political gaffes, missteps, and embarrassing political moments are digitally captured and uploaded by audience members.

These amateur videos may originally be intended for viewing by friends or family. However, the viral elements that these messages contain (such as humor, surprising information, and ridicule) allow them to become viral in an unexpected and accidental fashion, creating real political consequences for candidates. Some examples that fell in this category include Senator George Allen and his “macaca” comment in the 2006 Virginia Senate race, and Governor Rick Perry, who forgot the name of the federal agencies he wished to cut during a televised debate of the 2012 GOP presidential primary. A video of Governor Mitt Romney’s unscripted “47 percent” comment in a fundraiser created a firestorm for his campaign.

Conclusion

Whether used in the context of electioneering or facilitating social movements and carried out in a strategic or organic fashion, relatively low-cost and high-impact viral marketing messages represent an “equalizer” that could potentially level the playing field for many political actors. However, as seen in numerous examples in the past, effective viral marketing alone does not necessarily lead to success, suggesting that ultimately politics occur on the ground, not on the Web.

Politicians and organizations must find ways to translate the publicity and passion generated online into meaningful and significant offline actions. One of the many reasons that Barack Obama won the 2008 presidential election was his campaign’s ability to convert online followers into donations and votes. Similar arguments can be made about the success of the Arab Spring revolutions and failure of Invisible Children to create turnouts for offline events. An actual organizational network is the critical factor that carries the success of viral marketing efforts to the next level.

Although viral marketing is a promotional technique once primarily used in the business realm to promote a brand, product, or service, the adoption of social media tools by politicians have made them important communication and strategic tools. With the rapid growth of social media and digital communication technologies, one can expect that viral marketing will continue to shape the contemporary political process in different shapes and forms.

Viral Seed/Viral Lift

Viral seed/viral lift refers to a ratio between total and paid clicks on an online media asset. Viral seed refers to paid clicks, or clicks coming from advertising that a campaign paid for. Viral lift is the total number of clicks on the asset. As a ratio, lift is described as the total number of views divided by the number of paid views. A ratio of

one would suggest that there was no viral lift. Viral lift is used to understand the placement of a story on a Web site and the propensity for that information to be shared by others. This is important for understanding social media and political communication because it provides a clear way of relating paid content to word of mouth. In this sense, the viral lift-seed ratio is not an approach to purchasing advertising but is a specific metric that can be used to evaluate the diffusion of information.

A popular form of online advertising pricing is cost-per-click, or CPC. This only charges an advertiser when a user clicks, which is distinct from impression- or CPM-based pricing, where an advertiser pays for the number of times their advertising appears on a Web site, regardless of user activity. The viral lift ratio provides a way of evaluating the number of clicks that a media element has received, and the propensity for that media to generate additional unique impressions outside the context of other conversion goals.

Often, conversion goals involve tracking a user's progression through a Web site experience until they reach a particular point, such as a donation receipt page. In many political contexts, the goal may be to spread information, without necessarily tracking a particular form of conversion task. In this sense, the benefits of the number of views that a campaign is paying for, through clicks, can be refined into a relatively simple number.

The viral lift-seed concept is situated between impression- and click-based pricing, depending on the pricing scheme employed for planting the viral seed. Effective use of analytics is critical for calculating viral lift; sources of traffic to the advertisement or post need to be documented for further analysis. Calculating viral lift can be done using a number of analytics platforms, or even by hand, given the basic data. Multiple links can be placed on different paid media platforms pointing toward a single content element, which would require that a campaign independently track their viral lift among multiple seed location vendors.

Seeding Strategy

An important lesson from other marketing areas that can be applied to social political communication is that the quality of seeded content is more

important than the quantity of content. Depending on the seed venue, it is possible or even likely that users will hide or block the seed advertisement if it is of inferior quality or oversaturated, defeating the purpose of the campaign. Unlike short advertisements on microblogging sites, content delivered via viral seed Web sites is typically longer, including more rich content elements. The more engaging and creative the experience, the more likely it will achieve lift. Given the dramatically different aesthetic potentials of different viral seed points, correctly tuning a campaign for a particular audience segment and medium is important. For example, a popular culture aggregator site would be ideal for a collage or stream of images into which an advertisement is embedded. This same strategy would be impossible with a microblog such as Twitter.

There are a number of possible viral seeding strategies. Generally, the best strategy for paid diffusion utilizes a hub of online social activity, often an aggregator or similar Web site, which has regular traffic and is suited for delivering information in a style suited to the campaign. Seed strategies are very similar to conventional social advertising strategies, using paid inclusion on pages or feeds. Seeders attempt to target persons who are important within their social networks, as well as individuals who are likely to push information between networks, or “bridges.” Selecting the correct sites for seeding is critical to the success of a viral advertising campaign. It is important to note that if the seed is widely deployed or broadcasted, the efficiency and word-of-mouth gains of the lift-seed model will be substantially diminished.

The concept of viral seed and lift runs counter to approaches to viral diffusion that would see viral spread as a spontaneous phenomena. Viral information spread is posited through the lift ratio as the reaction of publics to exposure to high-quality content. This can be useful in communication contexts where a clear return on investment is critical, and can counter the idea of online viral communication as a perpetual motion machine or source of free money or publicity. It is also important to note that the success of analytics and campaigns based on viral lift could increase the propensity of sites to curtail the use of free features, which might displace paid viral seed. In this sense, access to appropriate viral

seed is a prerequisite for effectively using the viral lift ratio to evaluate the success of an advertising campaign.

If adequate documentation has been produced, a user can effectively look for trends in the lift of the information. This allows fine tuning of the deployment of the viral seed. In an ideal situation, the lift would continue long after the seed had ended, because of the quality of the message and distribution to relevant members of the public: in this sense, the information can truly be considered viral. Continued access to the message or advertisement after the seed period is genuine word-of-mouth, which is the ultimate goal. This conception of the viral as the result of an effective seeding strategy is significant for understanding effective marketing through social media because it demystifies the process for evaluating the success of social advertising.

The viral lift/seed ratio offers an important vocabulary for discussing the use of paid media and providing a clear way of understanding the viral spread of information as existing in a direct relationship to the paid diffusion of information. Refining the particular viral seed strategies employed and the quality of seeded texts will be critical for campaign success using the viral lift ratio as an analytical tool.

Virtual Environment Technology, Immersive

Immersive virtual environment technology (IVET) is a collection of computer hardware and software used for the design of immersive environments (IVEs) that cause its users to perceive themselves as existing in and interacting with real-time, real-life surroundings. Immersion in an immersive virtual environment (IVE) results in a psychological state in which an individual believes him or herself to inhabit a setting that provides constant stimulation to which it is possible to respond.

IVET can also provide users with vivid sensory stimuli that allow them to access others' perceptions through simulation. Today's IVEs are primarily visual, auditory, haptic (involving touch), or a combination. User movement and speech are possible. IVEs are individual or collaborative. In such a shared IVE, multiple individuals are surrounded by the same IVE and are represented by virtual figures, also known as avatars. Because of the enabling features it provides, IVET is proving useful for many applications within an increasing number of domains. It brings 3D immersive visualization capabilities to the entertainment, architecture, engineering, and construction industries. Its use is also advantageous for research and training applications in education, health, and behavioral and social psychology. While a learning curve is necessary to acquire the skills to productively implement IVET, technology providers are increasingly providing training and costs are decreasing, making this technology accessible to an increasing number of institutional users.

IVET is still relatively early in its technological development. As digital computer, tracking, and rendering technologies have advanced and become relatively inexpensive, IVET systems have become more plentiful. Some users take a do-it-yourself approach to assembling the needed computer facilities, while others work with vendors who supply professional turnkey solutions capable of customization. World Viz is a provider of state-of-the-art IVET configurations that support complex interactive simulations. The configurations they provide are examples of standard

applications. Some of the most common forms that IVETs take today are 3D immersive and semi-immersive display technologies using head-mounted displays and motion tracking systems. Among the systems provided by World Viz are an immersive Wide Area Walking System, Seated Virtual Reality, Viewable Projection Walls, and Multi-Screen Projection.

Virtual Environment Systems

The Wide Area Walking System is an advanced application providing the highest level of immersion that allows users, after putting on a head mounted display, to walk around an environment in full scale and naturally explore, making adjustments to features in their surroundings with a data glove or remote handheld device called a wand. An automatic motion tracking system synchronizes movement in the real world with that in the virtual world, creating the Holodeck illusion. Essential components are a stereoscopic head-mounted display, an automatic motion-tracking system synchronizing real-world movement with virtual-world movement, and hardware consisting of a configured workstation with graphics. Optional components that can be implemented as needed include a sound system, data glove or handheld input device to interact with virtual objects, an eye tracker, an appliance for biofeedback, a plug-in for avatar animation and interaction with motion capture, and augmented reality solutions overlaying video feeds with computer-generated imagery.

Seated virtual reality (VR), in contrast, is similar to the Walking System and utilizes the same features, including the Stereoscopic Head Mounted Display, but because it does not enable walking, a motion tracking system is not required. The Projection Walls System, like Seated VR, enables viewing without ambulation, but fulfills more demanding imaging quality requirements with equipment that continually responds to the viewer's head movements to provide a stable visual simulator while making it possible to interact with floating 3D virtual objects. This system, which offers only partial immersion, uses very different hardware. It does not use a heavy head-mounted display, but instead relies on a projector, projector screen, rendering machine, eye tracker, and optical motion tracker. Multiscreen Projection, like the Walking System, supplies an environment in which a user can move:

Marines training with a virtual reality system in a simulation center at Camp Lejeune, North Carolina, in February 2010. The system allows the soldiers to operate in a realistic virtual world displayed in a helmet mounted display while wearing a self-contained virtual reality system. The setup has no external tethers and a small joystick is mounted on the weapon.

It provides a cubical, room-sized, fully immersive visualization system for multiple users. This collaborative environment provides a complete sense of presence and interaction with virtual objects. It does not require heavy headgear or tethers. The system is extremely hardware intensive, and needs dedicated space. Choice of configuration is determined by the purpose of the application.

Applications

A major benefit of IVET is in the degree of realism it offers that is unequalled by other mediums. IVET allows users to experience intense sensory input firsthand. Researchers conclude that the mind accepts the illusion of realistic experiences for a temporary period of time because with IVET, virtual stimuli digitally recreate and extend human sensory capabilities. IVET provides users with dense layers of auditory, visual, and tactile information, giving them a strong sense of “presence,” a perception that the simulated virtual environment is real. IVEs can also provide a far stronger sense of social presence than other telecommunications media because within IVEs, signals can be conveyed among multiple actors via verbal and

nonverbal communication channels. Virtual social interactions can closely resemble face-to-face contact because of nonverbal information that can be conveyed, including physical proximity, facial expressions, and other contextual clues including setting. That is why some researchers are forecasting a marriage between social media and IVETs, but this is not yet an important trend.

IVET has many applications including the architecture, engineering, arts and entertainment, and construction industries where the 3D immersive visualization technologies it provides make it possible to walk through a full-scale digital model to understand layout and design features, enabling informed choices in early stages of design and preconstruction. IVET simulation capabilities are useful in the domains of education and training. They are also used for research, particularly in the areas of health and social and behavioral psychology.

Persky and McBride point out that IVET contributes three main benefits to traditional research settings. With IVET, it is possible to conduct experiments and simulations in true-to-life environments while maintaining the tight

control so vital for validity and generalizability. In other research settings, there is usually a trade-off between realism (which usually introduces numerous extraneous variables) and experimental control. IVET also makes it possible to present and manipulate objects and elements that are not available in real life because they are invisible, intangible, or immutable. They can dynamically represent objects and concepts that don't actually exist in the real world. It is possible in an IVE to change any physical or behavioral characteristic of a person, making it possible to maintain or isolate the effects of a particular variable. Implicit and covert behavioral measures for social and behavioral experimentation have traditionally been difficult to design and administer, but IVET makes it possible to expand them.

S. J. Ahn, M. T. Le, and J. Bailenson describe interesting social psychology experiments based on the embodiment of others' experiences made possible by IVET. Examples include the simulation of schizophrenic experiences; investigations into the changes in behavior that can occur when embodying other's physical traits, resulting in what is termed "the Proteus effect"; and a phenomenon called "perspective taking," a phrase for "walking in another's shoes," which can lead to an increase in concern for others in need by adopting another's state of mind. This last function may well turn out to be the most applicable to issues-based politics, advocacy, and social justice campaigns because it would permit actors in the political arena to "experience" the implications of public catastrophic events such as oil spills or nuclear meltdown, as well as private disasters like rape, poverty, bullying, sexual harassment, and other forms of social and political discrimination.

Developing and implementing a new IVET application is a major project requiring a significant expenditure of time, energy, and skill. Cost has now decreased to the point where it is in reach of many institutions that have budgeted for or have received special project funding for this type of application. IVET can run on PCs, but other hardware is necessary, depending upon the types needed for the configuration to achieve the particular purpose. A number of commercially available VEs are available for common uses, but original applications require custom programming work. Software packages to create VEs are

available, and costs are diminishing as the sophistication increases with the acceleration of computer power. Creating effective simulations and studies to use with IVET requires creative facility and pilot testing. The extent to which a naturalistic verbal give-and-take with virtual humans is possible is still limited with today's technology, and requires voice recognition and artificial intelligence programming. But with skill and planning, it is possible to create a scenario delivered with IVET resulting in a psychologically natural exchange. Such a scenario, once created, can be repeated as often as possible in the same facility, or others with the required equipment.

Virtual Private Networks

A virtual private network (VPN) is an extension of a local network that safely connects two or more points. It is a network technology that allows an extension of the local network secure over a public network such as the Internet. A

VPN permits computer users to send and receive data on the VPN network in the same way as they would by using smaller, shared systems (similar to local access networks, or LANS) or large public networks like the Internet. In both cases, people making use of the VPN enjoy the same set of options as those who plug into non-VPN networks, including operations that relate to functionality, security, and efficient network management. The key difference is that VPN-transmitted content is encrypted, making it an easy way to extend secure operations, even if they are overlaid onto a public network. On the surface, VPNs look like a purely technical workaround for extending Internet content privacy onto public transmission systems—a kind of privacy overlay into the riotously public Internet.

In this sense, VPNs have sometimes been described as “anonymity networks,” although post-9/11, the degree to which even VPN services supply true anonymity is increasingly debatable, as accusations of VPN service provider logging of network usage continue to escalate. Regardless of possible monitoring, the downstream applications of VPNs are becoming increasingly important in the political arena. In great part, this is because the second unique characteristic of VPN architecture is that much of the user’s identifying metadata is cloaked by the VPN’s operating structure. Although not 100 percent foolproof, especially in light of the technical capabilities of monitoring programs like Prism, in a VPN network, geolocation data and the Internet Protocol (IP) address of the originating user are not readily available to spyware, cookies, and most everyday forms of electronic surveillance. This is because the IP address that shows up is that of the VPN’s remote transfer location, usually found in a physically distant area from many of its network users. By looping their Internet traffic through a remote third-party player, VPN users can circumvent regional blocks, restrictions, or localized paid-for-content offerings because no one can tell where they are in the physical world.

The political dimension of VPNs, riffing off this commercial workaround, manifests in three interlocking ways. The first relates to press freedom and the timely coverage of breaking events, as well as the ability of both journalists and non-journalists to access Web-distributed information

of political, cultural, and/or social relevance. Oppressive governments of all descriptions have developed methods for blocking certain types of Internet content from Internet users within their boundaries. This practice is called “geoblocking.” VPNs offer a way to sidestep geoblocking because there is nothing about the VPN user’s apparent IP address that identifies that particular computer as physically located within the blocked boundaries. This is an absolutely crucial technique for journalists working in areas of political and social unrest, as well as for the political activists on whom they often report.

The second way in which VPNs can be applied within a political context is as an enabling mechanism for character assassination, reputational harm, or malicious intrusion. This relates to the cloaking mechanism that comes as part and parcel of the VPN’s nonpolitical, everyday architecture. Those wishing to circulate injurious commentary on public figures and institutions, including political ones, can hide behind VPN systems to avoid the legal consequences of their actions, even if they go as far as posting outright false and libelous assertions. The third politicized use of VPNs, however, has to do with hacking into high-level sites such as the White House through a series of VPNs, making it extremely difficult for law enforcement officials to trace the hacker via an originating IP address. This chain-link process also creates jurisdictional complications that can further slow or even stall detection, remedy, redress, and apprehension of suspects because each VPN site is located in a different physical place that requires a separate warrant, court order, subpoena, or similar document authorizing entry into that electronic domain.

VPN Requirements

The basic requirements of a VPN are: user identification, data encryption, key management, and multiple protocol support. VPNs must verify the identity of users and restrict access to those who are not authorized. Data transmitted over the public network (Internet) must first be encrypted so that they cannot be read. This is done with encryption algorithms such as DES or 3DES. VPNs should update the encryption keys for users, and should handle common protocols such as Internet protocol (IP) and packet exchange interred (IPX).

The only metadata that show up when searched by spyware, cookies, or electronic surveillance are from a virtual private network's remote transfer location, usually nowhere near its network users. For this reason, geolocational data and the Internet service provider address of the user are not traceable.

VPN uses a technology called “tunneling” when establishing communication between two points. The tunneling simply uses a special protocol (usually SSH) to create a tunnel along which all data move, from one end to another. This tunnel is actually the same information sent by the action, but encrypted with a secure communication protocol, which makes sure that the data cannot be seen by outsiders.

Another advantage of the VPN is to facilitate remote access to a local network. A classic example is employees who need access to the work network from their laptop when they are displaced. In his or her notebook, the employee has a VPN client program installed, and after entering a user name and password, connects to a VPN server located in the offices of the company, and thus has access to the network. Currently, because of its effectiveness and low cost, VPN technology is virtually used to allow remote access and connectivity between different actors and segments of the same local network, if the distance between it is too large to opt for a physical and real connection. If a home user would also like to have safe access to his or her home network from outside the home, he or can opt for VPN, but it can be a somewhat cumbersome and excessive solution. Organizations can use a VPN to reduce costs of WAN bandwidth while increasing connection speeds when using Internet connectivity high bandwidth such as DSL, ethernet, or cable.

VPN Types

Remote access VPN is perhaps the most used model, and is currently used by suppliers who are connected with the company from remote sites (e.g., commercial offices, homes, or hotels) using the Internet. Once authenticated, the remote user has an access level that is similar to the company's local network. Many companies have replaced dial-up (modems and telephone lines) with this technology infrastructure, although for reasons of contingency, they still retain their old modems. VPN point to point is used to connect remote offices to an organization's headquarters. The VPN server, which has a permanent link to the Internet, accepts connections from the sites and establishes the VPN tunnel. The branch servers connect to the Internet using the services of a local Internet provider, typically with broadband connections. This eliminates costly traditional point-to-point links, particularly in international communications.

Internal VPN is less widespread, but is one of the most powerful tools for use within a company. It is a variant of remote access, but instead of using the Internet as a means of connection, it uses the same LAN of the company. It serves to isolate zones and internal network services. This capability makes it very convenient to improve the safety performance of wireless networks (Wi-Fi). A classic example is a server with sensitive information, such as payroll, located behind VPN equipment that provides additional authentication and encryption, enabling only HR staff to access information.

Uses and Abuses of the VPN

VPN encrypts data that one sends and receives over the Internet, preventing another person who stands between sender and receiver from intercepting that information. The first uses of virtual private networks were primarily for business. The main advantages offered by this technology to companies are remote offices, connection between offices, connecting servers, connecting public servants and local network servers, security mechanisms, improving business processes, and traffic filtering.

One of the main uses of VPN is the creation of remote offices. This allows geographically distant users to make local network connections safely

and have all or part of the benefits of locally connected users. Thus, one can have access to shared file servers and network applications. One can also connect two offices (or more) so that all belong to the same network. Servers can be connected together through a permanent VPN for secure information sharing. VPNs allow public and internal servers (without access to the Internet), maintaining communication in all directions to securely exchange information. A VPN can significantly promote the agility of internal processes, improving competitive capacity in the industry. The traffic traveling through the VPN can be filtered and continuously monitored, as in traditional networks.

However, virtual private networks can also be used as a means of evading censorship by dissidents, or by countries prohibiting access to certain areas of the Internet or delivery of certain information. Using a virtual private network, users can skip Internet access restrictions imposed in some countries, and these networks provide users with full Internet access, simulating that the connection is occurring from abroad. They are a way to avoid censorship in a country. In addition, the ability to connect anonymously and securely via VPN is used to control and exchange critical files, business databases, and criminal files. Some countries, like China, Iran, and Pakistan, have proceeded to lock VPNs and communication encryption systems to prevent network users access or submit information not controlled by the government abroad. This ability of the VPN to encrypt data is what has allowed it to become an incredibly useful tool to bypass government firewalls in these countries where citizens cannot freely browse the Internet.

Vitter, David

David Bruce Vitter is the Republican Party junior U.S. Senator from Louisiana. In 2012, he was finishing the first third of his second six-year term in the Senate. His use of social media is expanding, but is far less than the use of other politicians.

Senator Vitter was born on May 3, 1961, in New Orleans to Audrey Malvina (née St. Raymond), who was a homemaker with a social work degree, and Albert Leopold Vitter, Jr., an electrical engineer, physicist, and ultimately a petroleum engineer. Both of Senator Vitter's parents were Catholic. Vitter attended De La Salle High School in New Orleans, from which he graduated in 1979. He then earned an A.B. in liberal arts from Harvard, which was followed by another undergraduate degree from Oxford University, which he obtained as a Rhodes Scholar. He then returned to New Orleans, where he entered Tulane University Law School. He graduated in 1988 with a J.D.

Entering into the practice of law, Vitter occasionally taught as an adjunct professor at both Loyola University in New Orleans and the Tulane University Law School. In 1990, Vitter married Wendy Baldwin, then a local prosecutor in New Orleans. They had four children—three girls (Sophie, Lise, and Airey) and a son (Jack). Their home is in Metairie, a New Orleans suburb.

Political Career

In 1991, Vitter was elected to the Louisiana Legislature's House of Representatives. Taking office in 1992, he served until 1999. While in the legislature, he fought for ethics reform and for term limits. He was successful in implementing term limit legislation, which had a strong impact on incumbent Democrat politicians.

A change of direction came in 1999, when Vitter ran for the 1st District Congressional seat vacated by Republican Congressman Robert "Bob" Livingston, Jr. Late in 1998, Livingston resigned his seat in the U.S. House of Representatives following an adultery scandal. The scandal surfaced during impeachment activities related to President Bill Clinton. Larry Flynt, publisher of the pornographic magazine *Hustler*, offered \$1 million for every scandalous sexual story that was sent to him about every Republican member of Congress. At the time, Livingston was the Speaker of the House elect, and was scheduled to replace Newt Gingrich; however, he resigned when the *Hustler* story of his affair broke.

In the May 1, 1999, special election to fill the Livingston vacancy, David Conner Treen, Sr. (1928–2009) received the most votes. Treen was a former Congressman and governor. In the first round of voting, he finished first with 36,719 votes (25 percent). Vitter was second with 31,741 (22 percent); David Duke, famous for his activities as a Ku Klux Klansman, came in third with 28,055 votes (19 percent); Monica L. Monica, an ophthalmologist, garnered fourth place with 16 percent of the vote, while a conservative Democrat, State Representative Bill Strain, came in in fifth place with 11 percent of the vote. In last place was the owner of New Orleans's minor league baseball team and an attorney, Rob Couhig, with 6 percent of the vote. In the special election runoff on May 29, Vitter received 61,661 votes (51 percent) to Treen's 59,849 (49 percent).

During the special election, Vitter refused to pledge himself to a voluntary term limit if elected. He refused on the grounds that, unless term limits were universal, they would only rob the district of effective leadership. His opponents characterized his stance as hypocritical. Following the special election, Vitter was sworn in as the 1st District of Louisiana Representative in Congress. The district is a suburban district of New Orleans that includes Metairie, where the Vitters live. It has increasingly become a safe Republican seat. Vitter handily won re-election in the 2000 and 2002 elections.

While serving as a member of the House of Representatives, he supported anti-abortion bills that included the 1999 bill prohibiting transportation of minors to receive an abortion; the 2000 bill banning partial-birth abortions; the 2001 and 2003 bills making it a federal crime to harm a fetus while committing another crime; a 2001 bill prohibiting using U.S. aid money to assist family planning funding in foreign countries; a 2002 bill to support health agencies that do not provide abortion information; and a 2004 bill to make it a federal crime to harm a fetus in the act of committing other crimes. He has supported many other bills on topics from oil drilling to education and civil rights from a conservative position.

In 2002, Vitter was considering running for the Louisiana governorship in the 2003 election. Term limitations stopped incumbent Republican Governor Mike Foster from another term. Vitter looked like a good prospect until June 2002, when a story about Vitter and his involvement with a prostitute was published in the *Louisiana Weekly*. A small newspaper with a circulation of only 5,800, it covered stories of interest to the African American community in south Louisiana and New Orleans. The story alleged that Vitter had a relationship with a prostitute. The reason for Vitter's withdrawal was the announcement that he and his wife were having marital issues.

U.S. Senate

In 2004, Vitter won the U.S. Senate seat that had previously been occupied by John Breaux, a Democrat. Most political observers believed that Breaux could have easily won re-election. Instead, Breaux endorsed Chris Johns,

the Democratic candidate who was from Breaux's home district. Vitter's campaign was managed by Daniel Wesley Richey, a political consultant from Baton Rouge. In addition, Louis E. "Woody" Jenkins, also of Baton Rouge, joined the campaign. Jenkins had run for the Senate three times, in 1978, 1980, and 1982. Together, Vitter's advisors had significant political understanding of what it would take to win the Senate seat.

Consorting with a prostitute from New Orleans again emerged during the campaign as an accusation against Vitter. This time, Vitter denounced the accusation that he had a lengthy affair with a prostitute as just dirty Louisiana politics. He categorically denied the allegation. The accusation came from a member of the Louisiana Republican State Central Committee. This kind of accusation against a member of one's party seemed somewhat treasonous, because one party member was betraying another party member; however, the election was the "jungle primary." In Louisiana, the nonpartisan blanket primary is called the "Cajun primary" or the "jungle primary." A blanket primary election allows voters to choose between candidates from different parties. As a consequence, two candidates from the same party may be running against each other.

The scandalous accusation against Vitter did not prevent him from winning. His Democratic opponent lost with 29 percent of the vote to Vitter's 51 percent. The remainder of the vote was divided between the other candidates. The election made Vitter the first Republican from the state to be elected to the U.S. Senate since the Reconstruction election of William Pitt Kellogg in 1876.

To run his home office in Louisiana, Vitter recruited Michael Futrell of Baton Rouge to be his state director. Futrell, a lawyer and politician, was a former officer of the U.S. Navy who served as a commander on nuclear submarines. He managed the local and statewide "case work" or constituent service for Vitter until 2008.

In Congress, Vitter had developed a reputation as a "wonkish" conservative who was a champion of family values. Members of Congress play different legislative roles. Those like Vitter, who bury themselves in legislative routines and detail, are usually called "ritualists" by political scientists; in contrast to the "tribunes," who spend time with reporters preaching up their issues.

Legislation he sponsored included a 2005 "lock box" on Social Security; several offshore oil exploration and production bills; an alternative energy resources bill; pharmaceutical bills; and others including the post-Hurricane Katrina Louisiana reconstruction bill. Among his foreign policy positions were support for Israel, keeping a ban on travel to Cuba, support for India's nuclear program, and support for trade with China. As a senator, he also championed a constitutional amendment for term limits three times.

After Hurricane Katrina wreaked havoc on wide areas of Louisiana, Mississippi, and other parts of the Gulf Coast, the storm was followed by Hurricane Rita, which contributed even more damage to Louisiana. Vitter, along with the other members of the Louisiana congressional delegation, sought a wide variety of governmental aid to restore the state and region and provide assistance to victims of the storms. Historian Douglas Brinkley describes Vitter's legislative and political efforts to aid the people of Louisiana in his book on Hurricane Katrina, *The Great Deluge* (2006).

After months of keeping a low profile, Vitter was exposed in a scandal involving the "D.C. madam," Debora Palfrey (1956–2008), who operated an escort service. Convicted of racketeering and other charges, Palfrey committed suicide shortly before her prison term was to begin. Among her list of prominent clients was Senator Vitter. On July 9, 2007, he admitted that he had been a client of her escort service. The scandal ruined his chances for higher national office, but it did not end his political career.

Returning to Louisiana to meet with his constituents, Vitter denounced the practice of bailouts that were proposed to aid the big three automobile manufacturers in Detroit. The price tag of \$15 billion was opposed by Republican senators in "right-to-work" states where automobile assembly plants were likely to move. Since then, Vitter has opposed other bailouts.

In 2008, Vitter began assembling a campaign war chest for the 2010 election. In 2009, he raised \$750,000, and in 2010 \$2.5 million. Because of the D.C. Madam scandal, a number of people were proposed as candidates, including the stripper Stormy Daniels. However, despite possible minor opposition, all went well for Vitter.

To win a second term in the Senate, Vitter first had to block Republican Party opposition. His Republican challenger was Chet D. Traylor of Monroe, a retired associate justice of the Louisiana Supreme Court who was engaged in private practice. Vitter emerged the winner in the August 28, 2010, primary election with nearly 90 percent of the vote. In the general election, he faced Democratic Party nominee Charlie Melancon of Napoleonville.

Holding the Louisiana 3rd Congressional seat in the U.S. House of Representatives, he supported conservative issues, opposed some of President Obama's legislative proposals, and was the leader of the fiscally conservative Blue Dog Coalition in Congress. He captured just 37.7 percent of the vote, whereas Ernest Wooton and half a dozen other candidates garnered about 6 percent of the vote to 56.6 percent for Vitter.

Social Media

Vitter's campaign media has until recently been traditional. Yard signs and other physical media for campaigning have been standard. However, since well before 2010, Vitter has been using social media. His Senate office Web page encourages supporters to sign up for e-mailed newsletters. Video feeds are also available. He has a Facebook page, and uses Twitter and Ustream. His Twitter account was used in August 2012 to send an inappropriate tweet late at night to a 20-year-old college woman. It was quickly deleted, but still made the news. He has also appeared on Internet radio talk shows and writes on his "Bayou blog." His use of social media is expanding, but not as rapidly as other politicians.

Vlogging

Video blogs ("vlogs") enable people to express themselves on a global scale in a relatively low-cost way. From stylized montage to direct camera address, video bloggers have discussed issues, participated in debates, supported candidates, engaged in political parody, and tracked candidates to capture gaffes during campaign speeches. Politicians have used video blogs and distribution sites such as YouTube to announce their candidacies and to broadcast traditional media content such as political ads. Candidates have also used video to share their private lives. The pressure for candidates to publicize aspects of private life is reinforced in socially networked, online environments.

Video makers have used official campaign footage in mashups and remixes to create persuasive political commentary. In addition, "trackers" (also called opposition videographers) working for candidates may bring cameras to live events and record an opponent's gaffes. Such mistakes may have serious consequences on a political campaign.

A well-publicized example involves the so-called macaca incident in which Senator George Allen uttered a racial slur toward S. R. Sidarth, an Indian American campaign worker who had brought a camera to a rally during the 2006 Virginia Senate election. Calling him a "macaca" and "welcoming him to America and the real world of Virginia," Allen later claimed that he did not know the meaning of the word. His gaffe was captured on video and uploaded to YouTube, where it received more than 400,000 views, and

is believed to have played a role in him losing the election and derailing his presidential aspirations. Another tactic includes surprising candidates on the street and asking them questions about past actions, such as attending high-profile parties, to hold them accountable for their behavior.

Although some scholars believe that the democratized and low-cost aspect of video is changing the landscape of civic discourse, others remain more skeptical. The balance between official candidates and individual citizens posting on political matters is difficult to assess because of YouTube's ever-changing set of videos. Recent studies suggest that "macaca" or "gotcha" moments comprise only a small fraction of the political content posted to YouTube. One study of the 2006 and 2008 Senate races showed that the majority of political content posted to YouTube was repurposed traditional political ads, rather than citizen discourse.

Studies suggest that video bloggers participate in political debates. Research on nearly 8,000 videos submitted to a 2007 CNN–YouTube debate revealed that many videos contained questions that, although simply phrased, demonstrated knowledge of political issues and pushed candidates to articulate a response to a question, rather than relying on talking points. Another YouTube study showed that during the 2008 U.S. presidential election campaign, numerous videos appeared that included commentary, discussion, and debate, as well as official campaign materials.

Video bloggers may discuss civic concerns in ways that connect personal experience to politically relevant discourse. Several factors are considered important for understanding the potential of video blogging on civic discourse. The first factor concerns the need to develop media literacies in order to craft substantive messages, rather than relying on spectacle. Some scholars believe that citizen journalism through video has not lived up to its potential and remains mired in "gotcha," celebrity stalking, and video bystander behaviors during crisis moments. Others claim that video bloggers have successfully focused attention on key problems and personal experiences in their community that connect to larger debates and policies on issues such as environmental concerns, network neutrality, teen suicide, and neighborhood development. Further study is needed on YouTube and personal video blogging sites to

determine the extent to which the medium is used for substantive civic discourse and how it connects to political action.

In addition to the need to improve media literacy skills, other factors required to assess video blogging's potential include commercial and governmental support of video exchange. Individual videos and YouTube as a whole have reportedly been blocked for various lengths of time in countries such as Afghanistan, Armenia, Bangladesh, China, Indonesia, Iran, Libya, Morocco, Pakistan, Syria, Sudan, Thailand, Tunisia, Turkey, and the United Arab Emirates.

The bans have occurred in response to controversial videos containing inflammatory religious material or political protests. Commercial concerns include the viability of distribution platforms that rely on advertising. Advertisers are often hesitant to display ads next to uncontrollable vernacular videos. Although video blogging has been used to connect personal experience to political action, numerous factors including media literacy skills, computer and network access, governmental bans, and commercial restrictions are important factors for assessing the potential of video blogging in political and civic arenas.

Vote Different

Vote Different is a political remix video (PRV) that was created in light of the 2008 U.S. primaries by an individual not connected to any of the formal political campaigns, a form of user-generated content (UGC). This video mixes the 1984 Apple launch commercial of the Macintosh computer with images and sounds of Big Brother replaced with material from a Web video of Hillary Clinton, who at that time was a U.S. presidential candidate. The video is regarded as one of the first successful PRVs distributed via social media. Characteristic for most PRVs is the relative ease of creating such a video because it was created in a few hours using software accessible to everyone on a regular computer. The video was shared via YouTube and reached an enormous audience (2.5 million views within the first six months; by the time of the election in November 2008, it had received 5 million views). Furthermore, this phenomenon exemplifies the power of PRVs regarding their potential to voice social and political commentary via the remixing of popular culture.

Philip de Vellis created the *Vote Different* political remix video, also known as *Hillary 1984*, in 2008. By creating the video, uploaded to YouTube under the pseudonym ParkRidge47 on March 3, 2007, he voiced his opinion about the U.S. primaries that year. According to an interview with *First Monday*, he chose the PRV format because it was easy, and he could address those who were already interested in politics and felt an affiliation with Apple. Another motivation was born from his frustration about the way that politicians were using broadcasting media like YouTube. Peter Leyden concurred with this view when stating that this video signaled the end of the broadcast era.

De Vellis was active in the political field as a strategic communicator at Blue State Digital. He was irritated that the political field kept using sites like YouTube as broadcasting machines when these media had so much more to offer. De Vellis felt that the political body did not take its

audience, or rather citizens, seriously. A dialogue should exist between the politician and the citizen, but instead the one-way communicative street of the political machine kept itself alive via a different medium, social media. De Vellis resigned from his position at Blue State Digital after it became known that he had created the video.

The success of the video, according to de Vellis, was because it was truthful. Furthermore, the use of material from popular brands such as Apple and images and sounds taken from popular culture meant that many people could instantly relate to the imagery. In order to understand the video, the viewer was required to know who Hillary Clinton was and her role in the political arena. Furthermore, the viewer needed to at least know of the original Apple advertisement in order to fully appreciate and understand the political commentary offered by de Vellis in *Vote Different*. The *Vote Different* video inspired others to create PRVs, and opened up a new dialogue.

This showed the potential of such forms of political commentary by instigating discussion in the political arena and the public sphere. This also relates to de Vellis's key argument, as he stated more than once that he was convinced that politicians could inspire good debate. The format of the PRV then allows the political field and the public to interact with each other via that material. In this way, de Vellis argued, the political game has changed forever: The old political machine is over, and politics are now in hands of the ordinary citizen. Everyone can create something in their living room and send it out to an audience that potentially amounts to millions of viewers. This view is shared by others. Chuck Tyron argues that remixing popular culture offers the means to the general public to offer commentary on politics in general, and political campaigns specifically. He also adheres to the notion that the use of images and sounds from popular culture allows for a new form of intertextual parody. Jonathan Gray refers to this as critical intertextuality. While *Vote Different* is not a parody per se, de Vellis used the techniques of critical intertextuality to challenge the mainstream political argument that Hillary Clinton's nomination for presidential candidate was inevitable.

VoteBuilder.com

VoteBuilder is the Democratic voter database used to keep track of volunteers and voters so that local parties can communicate with constituents and encourage them to vote on Election Day. VoteBuilder is supported by NGP VAN, the leading technology provider to Democratic and progressive campaigns and organizations. NGP VAN serves thousands of campaigns and organizations, including all national Democratic committees, thousands of Democratic campaigns, and hundreds of labor unions and progressive and nonpartisan PACs.

Beginning in 2002, the Democratic Party developed two databases—DataMart, containing the records of 166 million registered voters, and Demzilla, a smaller database used for fund-raising and organizing volunteers. In early 2007, the Democratic National Committee (DNC) replaced these with VoteBuilder. Described as a "state-of-the-art nationwide voter file interface," the Web-based tool is designed to ensure that Democratic candidates from the national party to the state parties have access to the tools needed to help them win elections. As Howard Dean said at the time, "VoteBuilder will enable users to more easily and effectively sync data automatically, and facilitate the swapping of data between state parties and the DNC, thereby providing state parties and

candidates with the most up-to-date and accurate voter data available. As an example, the DNC will be able to create an updated nationwide list of voter contacts on a daily basis."

VoteBuilder is based on the precinct as the basic building block because speaking to neighbors is viewed as an effective way to turn out and win elections. Effective precinct organizing has the most potential to increase votes and win elections. The basic idea of precinct organizing is to recruit about five volunteers in each precinct. Over the course of the campaign, those volunteers identify about 100 voters who are likely to vote for the candidate, but may not be reliable voters. On Election Day, each of the five volunteers are responsible for making sure that about 20 of those voters go to the polls on Election Day. This is also known as flushing, and can add up to about 100 extra votes per precinct. In a U.S. congressional district with 200 precincts, that is 20,000 extra votes, which will make the difference in most elections. There is a great deal of work that goes into recruiting volunteers and identifying voters, but this is the most effective way to win elections.

VoteBuilder contains information on all voters in a state, including name, voting and mail address, party, age, phone number, and voting history. Some states include other key targeting data, including likely occupation, ethnicity, religion, and marital status. The voter lists and other information are updated three or more times a year using voter registration data from the state's secretary of state. Additionally, the basic voter registration information is enhanced with data obtained from other sources (including campaign activity), such as additional phone numbers, address corrections, certain consumer information, issue or candidate support tags, and other targeting data. VoteBuilder can be used to create lists of likely volunteers and then call or knock on their door to recruit them to attend events and help contact voters by phone banking or knocking on doors. The system can be used to create walk, mailing, and phone lists for subscribing campaigns. Data can be entered by logging into VoteBuilder through a regular computer and Web browser, or through applications run by handheld devices such as iPhones, iPads, iPod Touches, or Palm Pilots.

MiniVAN Touch is a smartphone app that currently works with Apple iPhone, iPad, and iPod Touch, and is under development with other platforms like Android. MiniVAN Touch allows Democratic organizers to contact potential volunteers and voters, record the results of each contact, and upload that information to the central voter database, without the need to pick up printed walk sheets. It also eliminates manual data entry. One may download the free MiniVAN Touch app from iTunes. Qualified Democratic candidates for any office in a state, whether statewide, congressional, countywide, or smaller, may access VoteBuilder if they sign an agreement with the state Democratic Party and pay the scheduled fee (in accordance with FEC guidelines).

trust in government and elected officials, cynicism toward the voting process, the inability to perceive meaningful social and economic change, a lack of political knowledge, media influence, and a growing disinterest in political issues are just a few of the explanations attributed to the growth of voter apathy. Statistics from the past few years show that the number of eligible voters who have abstained from voting has remained stable.

Statistics provided by the U.S. Census Bureau reveal that from 1968 to 2008, less than 70 percent of all eligible voters in the country voted for president. Of those eligible to vote, less than half of 18 to 24 year olds voted. Similarly, according to Elections Canada, voter turnout in Canada has been under 70 percent for nearly 20 years, reaching an all-time low of 58.8 percent during the October 2008 election. As in the United States, less than half of those between the ages of 18 and 24 voted: 37 percent in 2004, 43.8 percent in 2006, and 37.4 percent in 2008. As indicated by the statistics, voter apathy appears to be an issue for Western youth; particularly those in North America. Many primarily associate democracy with the act of voting. However, despite the widespread concern of voter apathy among young people, evidence of the political use of social media is evident.

During the November 2012 presidential election in the United States, many citizens, varying in age and gender, used Facebook to indicate which candidate they preferred, in conjunction with their political affiliation. Those who were behind Mitt Romney and the Republican Party were displayed in the following Facebook pages: Mitt Romney (12,109,198 "likes"; 2,521,110 talking about); Mitt Romney Central (107,186 "likes"; 59,270 talking about); and Vote Mitt Romney (12,500 "likes"). Likewise, President Obama had his share of supporters on Facebook: Barack Obama (32,191,139 "likes"; 2,628,859 talking about); Barack Obama 2012 (51,439 "likes"); and Vote for Barack Obama in 2012 (85,142 "likes"). While it is impossible to determine whether or not all of the eligible voters that participated in Facebook actually voted, the results are somewhat indicative of the actual election results, because President Obama was re-elected, winning both the electoral college and the popular vote. These results mirror suggestions that the political use of social media was evident during the prior U.S.

Voter Apathy

Voter apathy is the notion that some eligible citizens choose not to exercise their legal right to vote in elections. For a number of different reasons, these individuals willfully abstain from their democratic civic duty by not voting. A lack of

Voters in line at a polling location in La Crosse, Wisconsin. In November 2010, the U.S. Census Bureau reported that only 21 percent of 18-to-24-year-old U.S. citizens voted, compared with 61 percent of people 65 years and older.

presidential elections in 2008, and helped galvanize Obama's eventual victory that year. Empirical evidence gathered by Derrick L. Cogburn and Fatima K. Espinoza-Vazquez, including qualitative data analysis from a number of social media Web sites, such as Obama's 2008 Web site, Twitter, Facebook, Myspace, and his Change.gov site, in addition to e-mails and iPhone applications, illustrates the successful use of Web 2.0 and social media by the 2008 Obama presidential campaign. Their analysis affirms that social media and new technologies help to increase political participation, including voting.

While many critics remain unconvinced, a number of scholars believe that social media have the potential to increase political participation and democracy. As a means to help counter voter apathy among young people in Canada, countless young Canadians took to the streets and social media and became involved in the "vote mob" during the 2011 federal election. Vote mobs derive from flash mobs, where groups of people use social media to organize a physical event. Primarily as a response to Canadian television comedic personality Rick Mercer's challenge to young Canadians to vote in the election, students from the University of Guelph created a vote mob and posted the video of their event

online, likewise challenging other young people to vote and other universities across Canada to create their own vote mobs. The vote mob videos went viral and galvanized the creation of numerous vote mobs across Canada. Even younger Canadians in grade school and high school created more vote mobs. Effectively, the main purpose of the vote mobs was to encourage and challenge eligible young Canadians to exercise their right to vote. Despite their efforts, in the 2011 election, the percentage of eligible voters aged 18 to 24 rose only minimally, to 38.8 percent. Ian Reilly suggests that although Canadian youth may like online campaigns, these actions have yet to translate to actual votes.

In both the United States and Canada, government studies into voter apathy among young people display a strong concern for this phenomenon. This concern is shared by many outside of the government, including countless youth who have turned to social media as a tool to help combat voter apathy. A short video made by Oscar-winning filmmaker Errol Morris titled *11 Excellent Reasons Not to Vote* addresses the issue of voter apathy and highlights the importance of voting as expressed by a number of young Americans. On a similar note, the group Apathy Is Boring, claiming to revolutionize democracy through art and technology, was created to counteract voter apathy among young Canadians. Many more examples reveal the growing use of social media in the fight against voter apathy.

Voter Demographics

Voter demographics have always been a key element of American politics. The 2010 Census made abundantly clear that racial and ethnic minorities, women, young voters, and gay people are dominating national growth and will for decades to come. Studies have shown that younger voters have tended to vote for Democratic candidates in recent years, galvanized in part, perhaps, by both Obama campaigns’ direct appeal to that age bracket, since growing support for conservative candidates is also evident among campus populations, as demonstrated by social media content and traffic.

According to the Pew Research Center Internet Report (2013), as of December 2012, 67 percent of online adults use social networking sites. Women use social media 9 percent more than men and people living in cities have the most social media activity, at 70 percent of the population. Furthermore, 83 percent of people aged 18 to 29 are social media users. In terms of racial and ethnic groups online, Hispanics lead with 72 percent engagement, and African Americans trailing at 68 percent, who are ahead of Caucasians at 65 percent. Despite being somewhat economically disadvantaged, 72 percent of adults with annual household incomes below \$30,000 use social networks, more than those with higher wages.

The most popular social network is Facebook, with 67 percent of adults using the Mark Zuckerberg–founded service. A distant second is LinkedIn with 20 percent, with Twitter coming in third at 16 percent, Tumblr falling last at 6 percent. The growing ubiquity of cellphones, especially the rise of smartphones and tablets, has made social networking omnipresent. A total of 40 percent of cellphone owners use a social networking site on their phone, and 28 percent do so on a typical day. Young people, blacks, Hispanics, the highly educated, and

those with a higher annual household income are more likely to use social networking sites on their phones than other groups.

Social media activities are more likely to be pursued by younger users compared with social media users who are 50 years or older. Younger users are more likely to post their thoughts about issues, post links to political material, encourage others to take political action, belong to a political group on a social networking site, follow elected officials on social media, and “like” or promote political material that others have posted.

Gender Gap

According to the 2010 census, there were 155.6 million females in the United States. The number of males was 151.4 million. Although the gender gap has changed over the years, women of all ages are more likely than men to identify as Democrats. Recent polls have indicated that 41 percent of women identify as Democrats, whereas only 25 percent of women identify as Republicans and 26 percent as independents. In contrast, 32 percent of men identify as Democrats, 28 percent as Republicans, and 34 percent as independents. Therefore, the gender gap continues as a significant factor in U.S. presidential elections, and the preferences of men and women have never differed more than in the 2012 election: Barack Obama won the two-party vote among female voters by 12 points, 56 percent to 44 percent, over Republican challenger Mitt Romney. Meanwhile, Romney won among men by an 8-point margin, 54 percent to 46 percent. That total 20-point gender gap is the largest that Gallup has measured in a presidential election since it began compiling the vote by major subgroups in 1952. Notably, Obama’s 12-percentage-point advantage among women is slightly less than the 14-point advantage he had over John McCain in 2008, while Romney improved on McCain’s performance among men by 8 points. Thus, the narrowing of Obama’s winning margin between the two elections, from 7 points to 2 points, can be ascribed mainly to men’s shifting more Republican.

The gender gap has been evident in presidential voting since at least 1952, though it tended to be somewhat muted in the 1960 to 1972 elections, averaging just 4 points. Prior to 2012, the largest gender gap in Gallup polling history was 18

points in the 1984 election, which saw Republican Ronald Reagan win a second term in office. Majorities of both men and women voted for Reagan in that election, but he won among men by 28 points (64 to 36 percent) and among women by 10 points (55 to 45 percent). It is unclear to what extent the presence on the Democratic ticket of Geraldine Ferraro, the first woman to be a major party's vice presidential nominee, had on the vote of women that year. Women have supported the Democratic candidate in each of the last six elections. Men favored the Democrat in only two of the last six, 1992 and 1996, and in only four of the 16 elections since 1952. Overall, since 1952, men and women have differed as to the party's candidate they favored six times, including 1960, 1968, 1976, 2000, 2004, and 2012. In 2008, McCain ran even among men, whereas women preferred Obama by a large margin.

At 85 years and older, there are more than twice as many women as men. People under 20 years of age made up over a quarter of the U.S. population (27.3 percent), and people 65 years and over made up one-eighth (12.8 percent). The median age is 36.8 years (male: 35.5 years, female: 38.1 years). Younger voters have tended to vote for Democratic candidates in recent years. Despite supporting Ronald Reagan and George H. W. Bush, the young voted in favor of the Democratic presidential candidate in every election since Bill Clinton in 1992, and are more likely to identify as liberals than the general population.

In 2012, young voters represented a greater share of the national electorate than four years earlier, once again voting for President Obama by a huge margin, boosting his re-election. Voters 18 to 29 years old represented 19 percent of all who voted. Obama captured 60 percent of the youth vote, compared with Mitt Romney's 36 percent. Headlines suggested a lack of enthusiasm among college students in the 2012 election, and polling showed, fewer were registered or planning to vote. That is one of the reasons why Obama's victory was smaller than his 66 to 31 percent win over John McCain in 2008. However, it is still the highest that any Democratic presidential candidate scored in 30 years among 18 to 29 year olds. John Kerry, for instance, only won the youth vote by 9 percentage points in 2004 (in that election, young people made up 17 percent of the electorate). So,

more young people turned out for the 2012 election, despite new voter ID laws and challenges by lawmakers to college students' ability to vote, and widespread confusion about state voting laws.

In general, new technology is making it easier for candidates to reach youth, and in turn, more young people are voting. Web sites such as Facebook and YouTube not only allow students who do not subscribe to newspapers or watch the evening news to stay on top of the polls, but also allow them to share their excitement over the polls and candidates. While voters under 30 years old respond to turnout tactics at the same rates as older voters, in some communities they are more difficult to reach, so targeting must take this into consideration. Efforts in ethnic communities found young people as easy to reach as older voters, and student areas and apartment building have dense residences that lead to very high contact rates.

Lesbian, Gay, Bisexual, and Transgender (LGBT) Voters

A 2011 report by the Williams Institute estimated that 4 million adults identify as gay or lesbian, representing 1.7 percent of the population over age 18. It should be noted, however, that pinpointing the precise size of the actual LGBT population is, and has always been, a difficult proposition, since many factors encourage its members to remain unforthcoming about their identities. In addition to the chronic under-reporting that this engenders, operational challenges associated with arriving at a consistent and comprehensive definition of the term abound, eventually generating estimates by well-respected sources that range from 3.4 percent of the American population on the low end (reported by Gallup in 2011) to the traditional 10 percent calculation based on the 1948 Kinsey Report, up to 11 percent if sexual identity is regarded as a same-sex attitudinal attraction, in addition to being "counted" as actual sexual behavior and/or permanent social identity. Part of the reason that there is such a wide range in statistics about the LGBT population is due to the challenges of defining "sexual identity," *per se*.

The recognition of LGBT status can hinge on an attitude, a behavior, and/or on the maintenance of a core social identity, resulting in a definitional issue that has always plagued social science's ability to quantify LGBT. Most

statistics are based on data from respondents who acknowledge being LGBT as a permanent and primary social identity. This excludes from the final tally those for whom same-sex relationships occur as part of their overall sexual history, but for whom it is not a central component of their overall social identity—for example, people who experimented with LGBT relationships at some time in their life and/or those who continue to engage in LGBT relationships, but for one reason or another self-identify as heterosexual. As Gary Gates notes in his report for the Williams Institute: “An estimated 19 million Americans (8.2 percent) report that they have engaged in same-sex sexual behavior and nearly 25.6 million Americans (11 percent) acknowledge at least some same-sex sexual attraction.”

Bearing in mind the likelihood of severe underreporting, estimates of same-sex-experience and/or attraction in the U.S. population, contained in the Gates report alone, range from 3.4 to 25.6 million Americans. Researchers on both sides of the gay rights issue have noted that the measurement procedure for determining the percentage of LGBT-identified Americans has not been significantly updated since the watershed Kinsey Report more than 60 years ago. Kinsey’s classic 10 percent rule, now being re-evaluated, would have calculated the current American LGBT constituency at approximately 31 million.

Lesbian, gay, bisexual, and transgender Americans mostly vote Democratic within the 70 to 77 percent range in national elections, according to national media exit polling. In heavily gay precincts in large cities across the nation, the average is higher, ranging from 85 to 94 percent. This trend has continued since 1996, when Bill Clinton won 71 percent of the LGBT vote, compared to Bob Dole’s 16 percent. In 2000, Al Gore won 70 percent to George W. Bush’s 25 percent, in 2004 John Kerry won 77 percent to George W. Bush’s 23 percent, and in 2008 Barack Obama won 70 percent to John McCain’s 27 percent. In 2012, Obama won 76 percent to Mitt Romney’s 23 percent.

Minority Voters

The United States is a diverse country, both racially and ethnically. Whites constitute the majority of the U.S. population, with a total of 223,553,265 in 2010. White Americans are the

majority in 49 states, with Hawai‘i the exception. The non-Hispanic white percentage tends to decrease every year, and this subgroup is expected to become a plurality of the overall U.S. population after 2050. Reports foresee the Hispanic or Latino population rising from 16 percent today to 30 percent by 2050, the African American percentage barely rising from 12.9 percent to 13.0 percent, and Asian Americans upping their 4.6 percent share to 7.8 percent. The United States had 310 million people in October 2010, and is projected to reach 400 million by 2039, and 439 million in 2050. It is further projected that 82 percent of the increase in population from 2005 to 2050 will be from immigrants and their children. Of the nation’s children in 2050, 62 percent are expected to be of a minority ethnicity, up from 44 percent today. Approximately 39 percent are projected to be Hispanic or Latino, and 38 percent are projected to be “single-race,” non-Hispanic whites.

The minority representation in the total population overstates its presence among eligible voters because the fastest growing minorities are either too young to vote, or are less likely to be citizens, even when they are in the United States legally. For every 100 Hispanic residents in the United States, only 44 are eligible voters 18 years and over and U.S. citizens. In contrast, 78 of every 100 white residents are able to vote. So, even though minorities are growing faster than whites overall, the latter are more heavily represented among eligible voters (71 percent) than in the total population (63 percent).

This disparity is even more relevant in many fast growing “new minority” states. In Nevada, whites comprise 51 percent of the population, but fully 61 percent of eligible voters. Other states where minority voters are strongly underrepresented include Arizona, California, Texas, and Florida. Further diminishing minority electoral clout is lower voter turnout. Usually, the share of eligible minority voters who voted was 15 to 20 percent less than for whites. Turnout rates were smallest for the fast growing Hispanic and Asian populations. As a consequence, the white share of actual voters is even larger than it is among eligible voters. Whites traditionally favored Republicans. The last Democratic candidate who was supported by the majority of whites was Lyndon Johnson in

1964. In recent elections, Republicans have found their greatest support among whites from married couples with children living at home.

African Americans make up about 12 percent of the American population (38.9 million). Fifty-five percent of them live in the south. From the end of the Civil War, African Americans primarily favored the Republican Party due to its overwhelming efforts in achieving abolition, particularly through Abraham Lincoln's Emancipation Proclamation. The south had long been a Democratic stronghold, favoring a state's right to legal slavery. However, as years passed, African Americans began voting for the Democratic Party, as Franklin Roosevelt's New Deal programs gave economic relief to all minorities, including African Americans and Hispanics. Support for the

civil rights movement in the 1960s by Democratic Presidents John F. Kennedy and Lyndon B. Johnson helped give the Democrats even larger support among the African American community, which consistently voted between 85 and 95 percent Democratic. Barack Obama managed to net over 95 percent of the African American vote in the 2008 election and 93 percent in 2012.

Hispanics or Latinos constitute 16.7 percent of the total U.S. population, or 52 million people, forming the second-largest ethnic group. The Hispanic population is young and fast growing because of immigration and higher birth rates. For several years it has significantly contributed to U.S. population increases, and this is expected to continue.

The Census Bureau projects that by 2050, one-quarter of the population will be Latino. The Hispanic population, particularly the large Mexican American population in the Southwest and the large Puerto Rican and Dominican populations in the northeast, have been strong supporters of the Democratic Party. In the 1996 presidential election, Democratic President Bill Clinton received 72 percent of the Hispanic vote. In following years, however, the Republican Party gained increasing support from the Hispanic community, especially among Hispanic Protestants and Pentecostals. With his much more liberal views on immigration, President George W. Bush was the first Republican incumbent to gain 40 percent of the Hispanic vote (in the 2004 presidential election). Yet, the Republican Party's support among Hispanics suffered losses in the 2006 midterm elections, dropping from 44 to 30 percent, with Democrats gaining in the Hispanic vote from 55 percent in 2004 to 69 percent in 2006. Democrats increased their share of the Hispanic vote in the 2008 presidential election, with Barack Obama receiving 67 percent. According to exit polls by Edison Research, Obama increased his support again in 2012, winning 71 percent of Hispanic voters.

A third significant minority is the Asian American population, comprising 18.2 million in 2010, or 5.8 percent of the U.S. population. They are by no means a monolithic group and had been a Republican voting bloc through the U.S. presidential election of 1992, in which George H. W. Bush won 55 percent of the Asian American vote. That is because, originally, the vast majority of Asian

The November 16, 1867, cover of Harper's Weekly was illustrated with a drawing titled "The First Vote." "All persons born or naturalized" as citizens were granted the right to vote with the passage of the Fourteenth Amendment in 1868.

Americans consisted of anticommunist Vietnamese refugees, Chinese Americans, Korean Americans, and socially conservative Filipinos who fled Ferdinand Marcos in the 1960s through the 1980s.

The Democratic Party made gains among the Asian American population starting with 1996, and in 2006, won 62 percent of the Asian American vote. Exit polls after the 2008 presidential election suggested that Democratic candidate Barack Obama won 62 percent of the Asian American vote nationwide. In the 2012 presidential election, 73 percent of the Asian American electorate voted for Obama's re-election. This is because of demographic shifts in the Asian American community, with growing numbers of well-educated Chinese and Asian Indian immigrants who are usually economic centrists and social progressives. The Asian American community's increasing number of young voters has also contributed to eroding traditionally reliable Republican voting blocs such as Vietnamese and Filipino Americans, leading to an increase in support for Democrats.

Voter Identification

Political campaign professionals often use practices and strategies reinforced by past experience and anecdotal data. New approaches to voter identification (including data mining and microtargeting) use a more scientific approach that utilizes statistical analysis to pinpoint voters. Advances in voter identification technology mix science with the art of politics. Combining new voter identification strategies with social media allows campaigns to find persuadable voters and tailor communication directly to them. This strategy is commonly referred to as microtargeting, allowing political strategists to understand individual voters outside of the confines of traditional voter labels (i.e., voting blocs based on geography, party, and demographics).

Voter identification using data-mining and microtargeting marks a change in the way that campaigns can be run. The presidential campaigns during the 2012 election season were the most successful in adopting this new strategy. There are a number of important distinctions between an advanced voter data-driven strategy and more traditional campaigns. First, these campaigns use large and complex databases of voter information and use a technique called data-mining to identify voters who are persuadable. Second, data-driven strategies shift communication from mass media to more specific forms of media (primarily direct mail and social media). Third, these strategies are

more concerned with voter mobilization, rather than mass voter influence.

Voter Databases

Voter identification information, at the most basic level, is a list of registered voters. The official public lists are maintained by each state's office of the secretary of state and affiliated election boards. In most states, voters will claim a political party (Democrat, Republican, or independent are most common). The length of time a voter has been registered and voting history are listed, although how they voted is not listed. Address, age, sex, and other basic demographic information is also listed. Public voter identification information is then supplemented and managed in large databases by campaigns and political parties. Strength of party affiliation, voting history (including who they supported), issues of importance, and constituency affiliations (like union or interest group memberships) are added to the voter identification database.

Large campaigns and political parties are often tasked with updating and maintaining voter databases. The Obama for America campaign, for example, used data from the 2008 election (including information from the Democratic Party and coordinated campaign field offices), and added to the database for the four years leading up to the 2012 campaign. Within the past decade, with the help of new technology like mobile devices and Web-enabled database interfaces, the national parties have taken greater interest in cultivating information and resources down through the ranks. Both the Republican and Democratic parties coordinate with field workers and campaigns at all levels to consolidate data obtained through direct voter contact (i.e., canvassing and mobilization efforts). Candidates at all levels can access database information through collective agreements with their respective political parties. In 2012, Republicans used a network called the GOP Data Center, and Democrats used the Voter Activation Network (also known as VoteBuilder.com).

Information is also acquired from government sources like the U.S. Census Bureau and third-party organizations like the National Committee for an Effective Congress (a progressive political action committee). More recent campaigns have also added psychographic information from

consumer marketing databases. Consumer data, including information on life stage and consumer confidence, adds depth to basic voting-behavior data. In addition, a new type of third-party data gathering harvests contact and descriptive information about a social media user's circle of friends as a built-in, but deeply buried, component of the terms of agreement service contract for some mobile applications.

The privacy implications of this are large because it means that one's personal information can be contributed to political datasets, without one's knowledge or permission, as a side effect of someone else's choice to contribute their information. At its essence, voter identification is a list and a database, but what is important and rapidly changing is how this information is used. For the 2012 campaigns, huge databases were compiled to understand each voter at the most complete level possible. Data-mining is the practice of pinpointing and segmenting potential supporters, beyond traditional targeting practices of precinct location and voting bloc affiliation. For example, Barack Obama's campaign used data-mining to successfully target specific households in the swing state of Ohio. In order for a data-driven strategy to work, however, campaigns are forced to adjust time-honored communication tactics.

Communication Strategy

The need for extensive voter rolls is a relatively modern concern for political campaigns. Elections in early American history dealt with only a small fraction of the population. Subsequent decades gave rise to a strong political party system, whereby voters were identified based on neighborhood and party affiliation. Modern campaigns must contend with growing diversity of the electorate, the increasing isolation of the American lifestyle, and the decline in the political party system. Collectively, voters who may have traditionally aligned with a political party or interest group or community are becoming more autonomous in their interpersonal communication and voting habits. Because of these changes, innovative campaign professionals are adapting their communication tactics and strategies to adjust to the changing political landscape. Political practitioners have traditionally lauded the ability of mass mediated campaigns to win

elections. If a politician wanted to win, he or she would need a strategy that emphasized buying television advertising and attaining earned media coverage. As such, the primary focus on the campaign was to raise enough money to pay for more television advertising than the opponent.

Social media and new technology are facilitating a change in this strategy, however. While television advertising is still an important component, the 2012 campaign marked a significant transformation in how voters were identified, persuaded, and mobilized. Mass media was used for overall messaging; social media was used to specifically target voters on issues important to them. Traditionally, microtargeted message strategies utilized direct mail. This medium allows for more complex messages that can be directed at small segments of the voting universe. Social media builds on what political strategists have learned using direct mail, and puts it in a faster, less expensive, shareable medium.

Candidates at all levels used social media to supplement their media plans. At the presidential level, both Romney and Obama used e-mail to send personalized messages, posted shareable pictures on Facebook, posted campaign updates on Twitter, and maintained YouTube channels featuring campaign ads. Obama hosted an interactive campaign event on Reddit. Social media was also used to create communities of support, utilizing a mediated version of interpersonal influence. Voters could see which of the candidates their friends supported, or could retweet candidate messages on their Twitter feeds. Obama and Romney sent out appeals through social media to get people active in the campaign. For example, appeals beckoned people to “like” the campaign on Facebook, talk to friends about the candidates, and drag people to the polls. Social media had the added bonus of creating excitement and accountability in supporters. Social media, combined with voter identification, aids one of the most critical components of every campaign—mobilization.

Mobilization

All indications from the 2012 election season suggest that social media is not taking the place of mass media; rather, it is serving a very different purpose. Data-driven campaigns and social media are used as mobilization tools and as extensions

of campaign field activities. While both Obama and Romney were spending millions on maintaining a presence on television, each campaign was also strategically targeting voters, down to the individual precinct. Mass media was used to guide the big picture message of the campaign, to maintain an air of legitimacy (in terms of competitiveness), and to raise money. Social media was used to mobilize supporters.

Campaign strategies focusing on mass media (using television advertising and earned media coverage) are most efficient at the highest level: in presidential races, and some high-visibility gubernatorial and Senate races. Lower-ticket races, from untargeted congressional races down to the state house races, can neither depend on saturating the airwaves with television advertising, nor attract much interest from the news media. These candidates focus on affordable advertising (usually direct mail and social media) and volunteer mobilization efforts. For the 2012 presidential election, the combination of voter identification and social media created a localized campaign strategy within the larger campaign structure for both Romney and Obama.

Before technological advances, campaigns would institute get out the vote (GOTV) strategies that focused on base groups and safe voting districts. With social media, targeted voters can be directly e-mailed to remind them to vote. They can also be tracked as they use social media to check in at polling locations and update their statuses to reflect their vote. Social media does not replace a well-organized field strategy; however, it makes GOTV efforts more efficient. It also allows networks of friends to encourage each other to vote (even if they are not directly targeted by the campaigns), thereby pushing turnout for candidates up and down the ticket.

Normative Implications

Evidence from the 2012 election suggests that there are positives and negatives in using data-mining, microtargeting, and social media. The intimacy of social media as a communication medium has the potential to motivate voters who would otherwise be disinclined to participate in an election. Both the Romney and Obama campaigns used social media to mimic interpersonal appeals for support. E-mails were designed to appear to

be sent from the candidates, campaign officials, or other high-profile surrogates. Messages were addressed to voters by their first names, and made personal appeals to the importance of their individual actions. Facebook and Twitter referenced friends who also supported candidates and issues. In 2012, the strategy helped candidates connect with those who appeared to be unlikely voters. These included young people and emerging demographic groups (like Obama's appeal to the Hispanic vote).

More precise targeting and bespoke messaging may also have the unintended effect of turning off voters. Relying on data-mining can be viewed as intrusive by the electorate, and seemingly personalized messages may be perceived as contrived and fake. Campaigns must also address privacy issues and the ethics of data-mining techniques. Additionally, attempts to mobilize voters can be matched by more nefarious attempts to suppress the vote. Another normative implication is the expense of acquiring and maintaining databases. The tactics are still the domain of big, well-funded campaigns and parties. Small campaigns or third-party candidates with few resources have limited access to databases, and rarely have the expert technicians to run the data.

Last, social media is potentially filling in where the news media is leaving off in terms of informing voters. Many factors, including the culture of news, are contributing to greater emphasis of horserace coverage of elections. This type of coverage is considered negative by some media scholars because the news is not functioning as a true information source or gatekeeper. The news media in the 2012 campaign season became obsessed with the notion of candidate momentum. Obama was perceived to have the momentum through summer and the conventions.

Obama's momentum was abruptly stopped at the first debate when Romney was judged to turn in a stronger performance. Obama's momentum was never really regained, but the Obama campaign team seemed relatively unconcerned. Both Obama and Romney believed that their data-driven campaign strategies utilizing social media would be the keystone to victory. Social media and microtargeting voters theoretically make momentum less important because the micromessage balances out attacks on the macromessage.

Speaking to people through social media allows campaigns to circumvent media frames.

Voter Privacy

The Voting Rights Act was signed into law in 1965 to ensure the protection of voting rights of Americans, giving minorities better representation in the polls. The United States has made tremendous progress in ensuring that every person's voting rights are guaranteed. However, in more recent times, a major concern of the public is that voter privacy is not as protected as it was in the past. Cracks have opened in the system of protections, in part because of the increasing use of new technologies.

The lack of privacy has been brought up by many different facets of the public, and affects both voter and candidate. This means that voters are not treated like people with rights to privacy in the details of their lives, but as numbers and statistics deemed either as an ally or threat to different campaigns and groups. The major organization that has been working to defend the Voter Privacy Act is the American Civil Liberties Union (ACLU), although the Electronic Frontier

Foundation (EFF) and others, especially the Electronic Information Privacy Center (EPIC), are also active in this regard.

From the time the Voting Rights Act was passed as legislation into law, minority voter registration and accompanying voter turnout sharply increased. The increase in voter turnout has been because of the greater access granted first by the removal of insidious state laws that prevented an extension of the franchise guaranteed under the Thirteenth, Fourteenth, and Fifteenth Amendments, and by the adoption of access laws such as the National Voter Registration Act of 1993 (Motor Voter Act).

As the franchise has expanded, the predictability of voter behavior by traditional means has fallen. Empowerment of disparate groups such as Evangelicals (brought en masse into the electorate by the Pat Robertson campaigns of 1984 and 1988) and the recruitment and registration of the Latino community have led to a much wider and more unpredictable electorate. Those whose livelihood depends on their ability to predict voter behavior have adopted new and sometimes questionable strategies to identify voters, create records of private information in large databases, and mine data for information about individual voters.

Secret Ballot

From the beginning of American democracy and the electoral system, the simplest way to ensure voter privacy was through secret ballots at the polls. The early system of balloting in the United States was very simple. In the two-party system, a ballot was reserved and color-coded for each party, and the ballots were dropped by the voter into separate boxes in the presence of the election officials (often party officials), who could easily see who was voting for whom or what. This system made recording votes by person possible, and was a huge support to the system of patronage and favoritism that made up the material benefits of the political party machines. Ward bosses would canvass precincts for voters for a particular slate of candidates, individual candidates, or political parties, offering jobs and benefits, or even bribes to those who supported the precinct or ward boss's agenda. To verify a vote, one simply watched the voter cast a ballot, and wrote down the person's name.

Opposition to the party machines led to a number of systemic reforms during the Progressive Era. These reform movements eventuated the nationwide adoption of the "Australian" or "secret" ballot for national elections, although primary ballots (because primary balloting was a function of the political parties, and then a "private" affair") still often took the old, openly public form. The introduction of the secret ballot was complete in the United States by the end of the 1890s. It was intended to preserve the right of any citizen to vote as their conscience dictated, without fear of retribution by an entrenched power structure. The assumptions/requirements of the secret ballot in the United States were, roughly an official ballot printed at public expense, on which the names of the nominated candidates of all parties and all proposals appear, distributed only at the polling place, and marked in secret. Several new practices in voting in the United States are in violation of one or more of these practices. Postal voting and electronic voting both violate the distribution clause, and there is no guarantee of secrecy for these methods of voting.

Political Databases

Under the system of a required secret ballot, the only person who could ever know their political opinions, beliefs, and values were the voters. In recent years, databases have been created from public voting records. While databases have helped in creating a streamlined system of voting, making it faster and easier to count votes, they have also created uneasiness among the public. Some of these databases include how one voted, whether one owns a gun, and even what medical procedures one may have had, providing massive statistical data on everyone who votes. Probably the most powerful, yet lowest key of these databrokers is Aristotle. Such information databases and companies have been powerhouse sources for strong political masterminds such as Karl Rove. According to numerous articles throughout the media, voter privacy is dead and gone.

However, the invasion on voter privacy is not limited to their check in at the voting booth; it also lies within the social media surge that has occurred over the last 10 years. Voters all over America are linked into various social Web sites such as Facebook, Twitter, and Tumblr, all of

which give the ability for large database and statistical companies the opportunity to obtain very precise readings of voters' likes and dislikes. Not only do they get public information that users allow anyone to see, but when a person "likes" an application or a certain page, they are handing over tons of private information without even realizing it. Though technically, user agreements include warnings that the data may be used by the first party for purposes other than the application, or even sold or used by third parties, few users read these "terms of use" notices and simply click "okay" to move to the application.

This does not even cover how Web sites can track a user's search history, but instead relies heavily on the problem of the public placing their private information on the Internet, making it easier for them to become a part of the voter statistical surge. It is no longer necessary to embed a crude keyboard marker or keystroke reader—the application can automatically mark site visits. If voters only knew how the information they were posting on social Web sites could be used and is used, they might not be so forthcoming with their private information. Although the argument for this is that people willingly put their information on the Internet knowing the risks that come with that decision, there is still a line to be drawn on methods of getting that information so that lives can be used for gain and profit. Because user profiles are private, companies and campaigns have to create applications or pages in order to gain access to a user's private page, therefore gaining the ability to know whatever they want about a person and use that information for their marketing strategy.

Another tool used to gather information on voters is by getting access to simple public records. The commercial use of voter registration records has become a very common tool for campaigns and large voter database collecting companies. Although the Freedom of Information Act has created clearer guidelines for who and how people can gain access to public records, these vary by state, and although one state may have more restrictive laws on gaining access, another may make it relatively easy. Even so, the collection of information through voter registration records has not been challenged, and cannot be dealt with accordingly until it is challenged. This can become a problem because campaigns are able to dig

deeper into the voters in their area through information that could be viewed as private. Many voters have no idea that items such as their race, gender, age, current and past addresses, and possibly even where they went to school are all available in public records. For many of these sources, the data builder need not array the delicate and complex programs needed to source social media. However, this information and access to it is useless if the majority of the public does not care that these details are available to just about anyone. The access to public records has been what political database systems thrive on to support broker organizations such as Aristotle.

The past 15 years have proven the effectiveness of these kinds of strategies in campaigns for those seeking office, as well as for those in the marketing and advertising world. The Internet has made their personal efforts far easier and more efficient. Now, campaigns have better access to voters and can find more content that will boost their political candidate. In addition, marketers are able to better target the demographic that is interested in their product. They can gain more details about their voters and consumers.

Through the use of typical Internet ploys such as cookies, donation forms, and mailing lists, campaigns and companies now have the ability to gain private information by using people. E-campaigning is another way for companies and campaigns to mine a wealth of personal information from their demographic of voters, including which Web sites they visit, which for a lot of people is extremely private information. "Electronic monitoring" is an off-putting term and concept to many voters, and could result in an even larger number of people who do not participate in the democratic process. Recent revelations about data-mining under the USA PATRIOT Act have heightened paranoia and insecurity.

Cookies

To fully understand the length to which voter privacy is threatened, it is important to know what methods are used: "Cookies," or "HTTP cookies," are tiny bits of data that are stored by the user's browser when a computer user accesses a Web site. When the user returns to the site, these data are sent to the server on which the site resides to record the visit. While many cookies

perform useful tasks, misuse, particularly in the area of recording a given user's browser behavior, is possible. Use of cookies is a tactic used by many different companies in order to gain more information on the people that visit their site. However, it is not cookies that track users, but specific "tracking" cookies and cookies that serve third parties, offsite data gatherers with no necessary connection to the site.

Because third-party cookies and tracking cookies collect information about what other Web sites that user is visiting, they are particularly useful to data gatherers. The information they gather is then sent back to the Web site database and used to help navigate and profile what other things people are interested in, besides their product or Web site. Not only do they collect where a user is going on the Internet, but they can also identify the user in order to improve their targeting for marketing, which is called building a "user profile." While this may seem an obvious violation of privacy, many Web creators argue that users are allowed to delete cookies through a simple process, or even turn off cookies altogether. Not all cookies are bad; some are very helpful for keeping user information safe, and to initiate authentication processes.

The commercialization of the process of profiling Web surfers based on what they click on has become a 21st-century phenomena. Companies have been built in order to track, through cookies, where a demographic of people visit and how often they do so, in order to build complex and definitive profiles on which people go where on the Web, and what they are typically (or in the case of individuals, specifically) interested in. In addition, these companies merge with other companies in marketing and campaigns in order to provide them with solid information on their demographic of people. For campaigns, this provides a way to target those who would vote for their candidate, as well as to find out how to convince people not on their mailing list why they should vote for their candidate. The result of this usage has been to unsettle some in the public and has led some to question the ethics of people who use these strategies. The counterargument is that this is simply an extension of the political research that campaigns have always done, and that better knowledge of the preferences and demographic

profiles of constituents (or potential constituents) leads to better service and representation.

Privacy Policies

The issue of voter privacy has not only been acknowledged by voters, but also by political candidates; it is an issue that is now used to bolster their campaign platforms. However, before candidates were held accountable for their part in violating voter privacy, there were a lot of unanswered questions, including what candidates did with all of that information once their campaign ended, including e-mails, names, and data on their voters.

Some campaigns handed over their voter information to other candidates, without any permission from the people whose information was collected. The presidential campaign of Newt Gingrich, for example, has not only used the information gathered during the campaign for private enterprises of the former candidate, but has also been sold to or shared with other causes and campaigns close to the position of the former candidate. The process of gathering raw data, "massaging" it into a useful array, and setting up targets (individual and collective) within these data is a long process, and it is less so when the data is simply shared by those seeking to achieve similar ends.

With respect to the growing skepticism of some voters, many campaigns and political candidates have developed privacy policies, clearly stated on their Web sites, which warn visitors of the data gathering practices used by site creators. However, these policies often do not reveal what third-party Web sites may be linked to the campaign Web site through donation links, or what might become of the data after it is gathered. So, the candidate may have attempted to create transparency and a guarantee that the voter's information would be kept private, but they often cannot control the eventual use, or may not even be aware of the pitfalls. This is still a gray area in terms of protecting the privacy of voters.

The future of voter privacy is up in the air. The lines between legitimate use and violations of privacy are not clearly drawn. The area of Internet use is a legal and statutory minefield for legislators, as they attempt to balance privacy concerns with freedom from unnecessary regulation. Items

that lie within the public domain are fair game for campaign profiling: Technology has simply made gathering it and making it useful far easier than before.

The questions that surround usage really focus on data that is not in the public domain, and that which is surreptitiously gathered without the user's knowledge. One argument is that when users knowingly place items on the Internet, particularly via Facebook and other social media sites, they do so with the understanding that these data may be vulnerable to outside use. Facebook has made great strides in keeping users informed of the dangers, and it is not the fault of the site if users choose to ignore the warnings. The counter-argument is that where use is hidden, or warnings are deceptively worded, the site has not been diligent in preventing abuses.

that impel citizens to cast their votes on Election Day. As political communication and campaign messaging becomes increasingly digitized, however, attention has shifted to the role of social media (e.g., Facebook, Twitter, Myspace, and Friendster) and the influence these communicative platforms have on voter turnout—the percentage of eligible voters who actually cast their votes in an election. Political campaigns that are operated on behalf of all parties, causes, and levels of office engage their constituencies through social media for an array of communicative purposes, including fundraising, sharing “unfiltered” information that bypasses news media and opponent framing, creating name recognition, and clarifying positions and stances. The influence of social media on citizens’ voting behavior, either directly or indirectly, has been more recently discussed in popular media commentary to the extent that voting may now be considered a social political behavior, rather than merely an individual activity.

Among the most well known social media applications with respect to voting intentions and voter turnout efforts is Facebook’s Polling Place Locator app and “I Voted” digital button and banner graphic. Each of these features have appeared on Facebook users’ “news feeds” on election day to provide a convenient reminder to vote on that day, as well as information on where to vote. Facebook’s data scientists claim that approximately 5.4 million citizens clicked the “I Voted” button in the 2008 election cycle, and thereby indicated their intention to vote; for the 2012 election cycle, that estimate grew to 9 million users.

Some social media users also talk about and display their voting activities on social media platforms by, for example, posting pictures of themselves wearing an “I Voted” sticker after leaving a polling station, announcing that he or she participated in the act of voting for or against a particular candidate or cause, offering reasons or justifications for why someone is or is not voting, and even taking a picture of their completed ballot and sharing it with their online social network (this action is actually illegal in many states). In other words, the impact of social media on voter turnout is not just on the number of people voting because of social media use, but also the perception and symbolic uses of social media for this act of democratic expression.

Voter Turnout

Scholars of communication and politics, professional political campaign practitioners, political candidates, and other observers of democratic activity have had a sustained interest in the factors

Users posting photos of themselves on social media wearing "I Voted" stickers and buttons and millions of people clicking on "I Voted" digital buttons and banners heightens perception of this democratic act.

There are numerous acts of political expression, but voter turnout is often connoted as being a barometer of the health and responsiveness of the body politic. Low voter turnout is generally seen as malaise and public disengagement from public affairs, whereas high turnout tends to be associated with an active and well functioning democratic system. That turning out to vote is normative is not only reflected in academic and popular press commentary, but also from anecdotal evidence from social media users on Election Day.

Many Americans do not vote, and social media can be utilized to convey this lack of action. This includes expressing disapproval toward individual candidates, more generalized critiques of the two major political parties and lack of viable third-party candidates, apathy and malaise toward the political process, and the attitude that one's vote does not matter. Moreover, just as social media modalities allow users the opportunity to communicate voting intentions with others, users can similarly opt out of voting-oriented messages by blocking or hiding friends and political topics. As such, the impact of social media on voter turnout may be more indicative of offline political communication: those who are already interested in politics and intending to vote have yet another means to communicate this information to others, whereas those who are indifferent or not politically inclined can remain separated from messages about voting

and the social elements created by social media platforms.

The relationship of social media and voter turnout entails some important caveats. First, social media's impact must be understood relative to other communicative modalities to which voters attend in the course of a political campaign and deciding to vote. Citizens can receive appeals to register and vote from a variety of information sources, such as people whom a voter encounters in offline contexts (e.g., a petitioner or pollster encountered in a public space), "conventional" get-out-the-vote efforts such as canvassing and phone calls, and mass appeals such as political advertisements and yard signs. Voter engagement initiatives such as National Voting Registration Day and MTV's Rock the Vote not only use social media sites but also on-the-ground volunteers who sign up individuals in public venues using paper and clipboards, celebrity appeals on television advertisements, and a variety of face-to-face activities by local nonprofit organizations and campaign staff.

Second, voter turnout is affected by a number of legal and regulatory factors that can overshadow social media effects. Most nations have certain age and citizenship status criteria that define their voting populations, including those that actively suppress the voting rights of certain religious, racial, ideological or partisan, and gender-based groups. Some countries enforce compulsory voting among their citizens, and others strongly encourage their citizens to cast their ballots based on social and collectivistic norms. As such, the impact of social media on voter turnout must be understood in terms of the political context in which such modalities operate.

Empirical Evidence

Empirical evidence suggests that voter turnout is associated with social media use. Self-report data from a variety of academic and nonpartisan research organizations describes many citizens announcing their vote choice on election day for candidates at all levels of elective office via social media, that they received persuasive appeals from their friends and family on a social media platform to vote a particular way, and that they had attempted to get others to vote in a particular way using social media tools.

Testing the direct influence of social media on voter turnout is a more challenging task. Recent undertakings provide some estimates about the direct influence of social media on voter turnout. Secondary analysis by the Pew Research Center about the 2008 election cycle, for instance, noted that citizens' use of Facebook and Twitter to read, discuss, and share political content with others was associated with higher turnout.

Systematic efforts to measure the direct influence of social media and voter turnout are also emerging. A collaborative undertaking between academic researchers and Facebook's data scientists has provided one of the most integrated efforts to date—one that has been widely reported in news media coverage. In testing the effect of Facebook use on voter turnout in the 2010 election cycle, Robert Bond and colleagues placed 61 million Facebook users into one of three randomized groups: (1) a social message condition (that is, users' news feeds provided a short message encouraging the user to vote, a hyperlink to find their local polling station, a clickable "I Voted" button, a counter showing how many other Facebook users reported that they had voted, and several thumbnail photos of their friends' profiles who had already clicked "I Voted"), (2) an informational message condition (such as a vote encouragement message, poll locator, button, and counter, but no thumbnail pictures or references to any of their friends), or (3) a control group (no messages or graphics about voting or polling station location or friends' voting activities).

The two treatment conditions were assessed in terms of whether and how users interacted with the graphics and message features provided by Facebook; users in each of the groups were also compared in terms of indicating on Facebook that they were going to vote, and their actual record of voting from publicly available records. Their results demonstrated that voter turnout was highest for the social message group. Notably, a contagion effect was described in which users in the social message group were more likely to vote when their "close" Facebook friends had previously expressed their intention to vote, and that information was conveyed in the thumbnail photos or "'x person' has already voted." Although results yielded a small effect size, the statistical

equivalent of Facebook's social message condition resulted in an additional 340,000 votes. A replication of this research design and assessment was implemented for the 2012 election cycle, although the results were not publicly available at the time of this writing.

Empirical assessments about the impact or effect of social media on voter turnout merit some caveats. First, social media may provide helpful voting information for those who are already active and registered, but current social media applications and practices have largely overlooked the process of registering new or disenfranchised voters. Facebook's polling place locator and "I Voted" digital button, for instance, do not provide users with information or functions for registering before a primary or general election deadline. Although it is plausible that social media platforms might collaborate with state and local officials and major party campaigns to increase the total number of registered voters and potentially increase voter turnout, such efforts are presently rare.

Second, measuring social media's impact on voter turnout necessitates that social media messages are examined over a period of time, not just on election day. In addition to absentee voting, many states allow their residents the option of early voting, sometimes almost a month before election day. If a substantial proportion of citizens are casting their ballot via early voting, without needing to be prompted by others in their online social network, estimating the effects of social media becomes more convoluted.

Finally, the measurements of social media use could also be problematic. Users could inadvertently indicate their intention to vote through clicking a graphic or posting a message through simple misuse of technology; users indicating that they intend to vote, but then not actually voting; or users indicating that they intend to vote or that they actually did vote at a point when it is too late to influence their peers' behaviors. Many voters come to the polls later in the day or early evening after they finish their workday, and they might not be telling their social network friends about this until some point later, when they have also gone to the polling place.

the Vote" drives. This technique has long been used by businesses to target consumers, and the Grand Old Party (GOP) was credited with first using this technique in 2000, when Alexander Gage convinced the Bush campaign to implement it as a way to contact individual voters. Subsequent presidential races saw both parties become increasingly entrenched in microtargeting techniques, with the Obama 2012 campaign possibly setting a new benchmark for the technique. Voter Vault was born from the 2000 presidential campaign success as an Internet-based database management system, and was used by the Republican Party from 2002 until 2012, when it was finally replaced by Data Center in 2012. Data Center was maintained by FLS Connect, which had also worked on Voter Vault.

Reince Priebus, Republican National Committee chairman, published the Growth and Opportunity Project in December 2012, to report on the committee's data management platform. Data Center will either be revamped or replaced by Liberty Works in 2013, a firm run by Richard Boyce, an associate of Karl Rove, though it is reported that Rove has no ownership or interest in Liberty Works. Data Trust, a separate company with close ties to the Republican National Committee (RNC), will exercise control of the list. Unlike the Democrats, who have centralized the processing of data through unofficially endorsing (since 2004) the company's Catalyst and Voter Activation Network (NGP VAN) with the program Vote Builder that now houses information on 180 million registered voters, the Republicans have splintered into a variety of data management providers, eliminating a central database, which some claim gives the Democrats an advantage.

For example, Steve Adler, a Rhode Island programmer who helped start NGP VAN, has switched sides and developed a system for Republicans called rVotes, which competes with Voter Vault/Data Center. Allegations over Voter Vault editing access misuse by party leadership led to the creation of the new Data Center. Complaints ranged from mining of newly acquired personal data for monetary solicitations to the state and national party, to poor voter updates in municipal elections. A major difference between Voter Vault and the new Data Center is no direct manipulation

VoterVault.com

Known as "microtargeting," voter databases are central to voter contact activity, including fund-raising, recruitment, issue tracking, and "Get Out

of data. A candidate can download a list and manipulate information on it, but the modified list cannot be reuploaded for other candidates to use. However, the new Liberty Works agreement allows access to voter files, on the condition that they update the data they use.

The Data Center system works similarly to Voter Vault. Applicants are screened by the respective State GOP, then the GOP candidate (or local chairman) is provided a user name and password that allows them to log into the Data Center Web site and access registered voters in a county or district. It provides for individual voter lookup, change of information, and the generation of reports and downloadable lists. According to Republican National Committee spokesman Sean Spice, the GOP Data Center contacted about 80.5 million voters in the 2012 election. Personal data frequently included in both Voter Vault and the Data Center database consists of: name, physical address, mailing address, phone number, party membership or affiliation, voting history (including federal, sub-national, primary, municipal, or special election voting history), absentee or military voter designations, source of voter registration, ethnicity or race, gender, and birth date or age range.

The new Data Center was redesigned as a big data warehouse by cross-matching the following public and consumer information: vote frequently, homeownership, hunting or fishing license holders, boat owners, occupation, charitable or political contributions, magazine subscription status, veteran records, property records, census results, the results of past telephone surveys, and the Postal Service's national change of address system.

These database systems are different from the Romney campaign's Election Day voter mobilization program (ORCA). ORCA is an application programming interface (API) for smartphones and tablets that directs users to a mobile-enabled Web site that does not require additional software to use. It is not an app available from the iOS App Store or Google Play. As opposed to the Data Center, ORCA enhances poll watching, where volunteers monitor polling stations tracking who voted in order to focus efforts on getting out the vote later on Election Day.

ORCA was conceived by Rich Beeson, the campaign's political director, and Dan Centinello,

Romney's director of voter contact. ORCA crashed on Election Day because of a variety of factors. It is unclear what effect, if any, it had on the "Get Out the Vote" effort of Romney, but the perception created frustration for volunteers. The Democrats used a system where volunteers would report voting information to a centralized national hotline called Houdini in 2008, and implemented a similar program called Project Narwhal in 2012.

Voting, Global Electronic

In many areas of the world, electronic voting or e-voting systems have been tried, and in some cases they have been successfully adopted; whereas in other cases, they are still being tested, have been delayed, or have been rejected. While experimentation with electronic voting continues globally, there is no consensus on whether e-voting technologies and systems are a step forward or backward in the election process, and even

among supporters of e-voting, there is debate about whether the degree of improvement is enough to justify the cost. Meanwhile, scholars and activists are striving to provide guidelines and procedures for safe and fair electronic voting.

Electronic voting is the casting of electoral ballots through electronic systems. Technologies employed in electronic voting have included: optical scanning voting systems, which use optical scanners to read marked paper ballots and tally the results; and direct recording (DRE) voting systems, which provide an electronic display for vote casting accessible by the voter through a button or a touch screen, and which also allow the electronic transmission of completed ballots to a central location for tallying and reporting. The management of electronic voting has included e-voting that is physically supervised by electoral authorities, such as machines at polling stations; and e-voting that is not physically supervised by electoral authorities, such as remote electronic voting. A voting machine is a combination of mechanical, electromechanical, and electronic equipment used to cast and count ballots, display and report election results, and produce and maintain audit trail information. Voting machines have different levels of usability, accuracy, and security. Remote electronic voting can be done from a personal computer connected to the Internet, a television device with an Internet connection, or a mobile phone.

Early Adopters

Brazil, the largest nation in South America, is a pioneer in electronic voting because since 2000, all votes in Brazilian elections have been cast through electronic voting machines. The Brazilian Supreme Electoral Court authorized the use of electronic voting technology in the 1996 municipal elections. The Brazilian government fully converted to electronic voting by means of over 400,000 kiosk-style machines in the 2000 national elections. Voters in Brazil use an electronic voting device with an integrated screen and keyboard that displays choices and prompts the voters to cast a ballot for each office. Voters need to press the number designated for a particular candidate on the keyboard. The candidate's picture then appears on the screen. Voters can confirm, reject, choose another candidate,

or start the selection process again. The voting machine tallies the votes, producing both digital and printed reports of the number of votes given to each candidate. Machines also produce a paper ballot that the voter can deposit in a box for a recount. Following the example of Brazil, other South American nations such as Argentina and Venezuela have implemented similar electronic voting systems.

No other country in the world has used electronic voting on as large a scale as India, although not all voting in India is electronic. With an electorate of more than 668 million, India would require over 1 million electronic voting machines (EMVs). Electronic voting was introduced in India in 1982, when it was experimentally used in the Parur assembly constituency in the State of Kerala. However, the Supreme Court of India struck down this election as illegal. Further legislative measures adopted in 1989 reopened the possibility for EVMs in elections. In 2003, all state elections were held using EVMs. In 2004 and 2009, EVMs were also available in the national elections for the Indian Parliament, and because a record 400 million voters cast their ballots electronically in the 2009 national elections, the tallying of results took just several hours. The EVMs built by the Electronics Corp of India and Bharat Electronics consist of two units, one for control by the polling staff, and the other for the use of voters. Voters press a button next to the candidate's name and symbol, and the polling officer records the vote. A light next to the button glows, and a short beep sound follows, indicating that the vote has been cast. The polling officer then presses a switch to clear the machine. The EVM comes in a reusable carry pack, and can operate on a battery power source in remote areas. Each EVM can record five votes a minute, or nearly 3,000 votes a day.

Estonia, a former Soviet republic and now a member of the European Union, has advanced the farthest in remote electronic voting. Since 2005, Estonia has conducted local elections as well as national parliamentary elections in which all voters can use Internet voting. Remote electronic voting in Estonia occurs during a three-day period, within the broader early voting period. Any Estonian voter who wishes to cast a ballot over the Internet needs a national identification card, the personal identification numbers (PINs)

associated with the card, and an Internet-accessible computer with a working smartcard reader. The Estonian Internet voter goes to a designated Web site and proceeds to authenticate the system. The person is prompted to insert the national identification card into the reader and write a first PIN. The voting server queries the voter registration database, and the person is then sent to a page providing a list of candidates.

The voter selects a candidate from the list, confirms the choice, and writes a second PIN. The completed ballot is encrypted, and the voter signs a digital version of an absentee ballot “envelope”; this “envelope” containing the voter’s identity is disassociated from the actual ballot when it is confirmed that the signature is correct and the voter has not also cast a paper ballot. A voting server verifies the digital signature, and if it is correct, it passes the encrypted ballot to another server, where it is stored for tabulation. If an Internet voter has also cast a paper ballot, the voter’s Internet ballot is electronically tagged so that it will not be counted on the night of the election. This complicated, but secure remote voting system is trusted by Estonians, but there is doubt that it could be replicated outside of this small and highly centralized eastern European nation.

Experimentation

Experimentation with electronic voting systems has been widely pursued on the European continent, yet in most European countries, such systems are not sufficiently accepted, too cost prohibitive, or not safe enough for overall adoption. In Germany, electronic voting machines were tested in the 2005 Bundestag elections on over 2 million voters, but the lack of public confidence in the Nedap machines, produced in Netherlands and already challenged in that country, led to a decision to discontinue their utilization. An electronic scan voting system was also tried in the 2008 state elections of Hamburg, but while its usability was demonstrated, surveys found public distrust, and plans for its further implementation were abandoned.

Italy, Spain, England, Ireland, Finland, and Norway have also piloted electronic voting systems at various levels in the past decade, but such systems have proven too expensive and not high enough in voter satisfaction to further proceed to widespread implementation locally and nationally. In

An electronic voting machine used during the 2005 Brazilian elections. Brazil was one of the first countries to vote electronically, and had fully converted to electronic machines by the 2000 national elections.

Belgium, electronic voting was approved by law in 1994, and electronic polling booths were put in place for the general elections of 1999 and 2003, and municipal elections in 2000. However, electronic voting provoked delays in voting operations in many localities in 2003, causing long lines at the polls and the absence from the polls of an estimated 10 percent of the electorate, in spite of Belgium’s compulsory voting system and fines for failing to do so; electronic voting has since not been expanded in this country. From the late 1990s to 2007, electronic voting machines were extensively used during elections in the Netherlands, although their effectiveness was contested by various groups.

After the 2006 parliamentary elections, a group called *Wij vertrouwen stemcomputers niet* (“We do not trust voting machines”) showed on Dutch television how the voting machines utilized in these elections, and produced by an autochthonous company named Nedap, could be manipulated in five minutes through a software exchange unnoticeable by either officials or voters. Subsequently, a Dutch court declared the use of Nedap e-voting machines unlawful, and the Netherlands returned to paper voting. In spite of such problems with e-voting in Europe, some partial successes have

been recorded in European countries with remote electronic voting. Elections in France utilized remote electronic voting for the first time in 2003, when French citizens living in the United States were given the option to vote for their representatives in the Assembly of French Citizens Abroad through the Internet. Over 60 percent of French voters in the United States chose to use the Internet, rather than paper ballots, and as a result of this success, all French citizens living abroad were able to use remote electronic voting in the 2009 elections. However, in the territory of France, local and general election voting is still done through paper ballots. Following France, Switzerland has also adopted remote electronic voting for citizens who live abroad, while maintaining paper voting for citizens living in its territory.

The several countries that have experimented with electronic voting systems in other regions of the world have encountered the same mixed results as in Europe. Australia has been testing various electronic voting possibilities for over two decades, including a successful open source Electronic Voting and Counting System (eVACS) in the Australian Capital Territory (one of the eight territories of this country). EVACS has been commended for its increased potential for voter participation for offering ballots in 12 languages, as well as its higher reliability for vote tallying than hand-counting of votes, although it is said to also have some minor problems such as difficult-to-use barcode readers and minor delays in displaying results on and after election night. Although generally trusted by the Australian public, electronic voting is still used by only approximately 10 percent of the Australian electorate.

In the Central American nations of Panama and Costa Rica, EMV systems with complex voter identification and ballot casting procedures were tested at local levels at the end of the 1990s and the beginning of the 2000s, but they were not nationally adopted because of lack of consensus among political actors and fear of electoral fraud. In North America, Canada and the United States have both tested electronic voting systems. Canada has employed electronic voting technologies since the early 1990s, but these have remained confined to the municipal level, and have more recently expanded partially at the provincial levels, while national elections remain

paper based. In the United States, both electronic voting machines and Internet election practices have been attempted since the early 2000s; however, controversies surrounding the use of electronic voting machines and problems with Internet voting in several presidential primaries have delayed their spread. In both Canada and the United States, civil rights concerns regarding the potential disenfranchisement of minority groups because of the digital divide, as well as security threat concerns regarding the possibility of denial of service attacks and voter identity theft have been expressed by opponents of electronic voting.

Electronic Voting Potential

Direct Democracy: Progress and Pitfalls of Election Technology (2010), published by the International Foundation for Electoral Systems and edited by international expert in election technology and administration Michael Yard, asserts that the mixed results of electronic voting systems are because of the difficulty to balance the benefits and the shortcomings of such systems. According to the report, benefits can include increased accessibility that e-voting machines can offer to persons with disabilities, a possible increase in voter turnout, and decreased opportunity for fraud or error by election workers who count votes and fill in counting and tabulation forms.

However, shortcomings can include the potential for lack of transparency, the difficulties in creating bug-free software, security vulnerabilities, and opportunity for an election to be manipulated by a small number of persons, or even by a single individual. In less developed countries, there are also concerns about lack of adequate infrastructure to support electricity and communication requirements, and improper storage facilities that subject equipment to environmental extremes. Given the intricacy of the issues related to electronic voting globally, this report and other research have provided guidelines for selecting an appropriate system and procedure to follow.

In terms of selection criteria, systems should be accessible, or with capability to enfranchise various voters while operated without long-term outside assistance; secure, or with capacity to provide protection from unauthorized access and from excessive loss from disaster or malice; accountable, or with the ability to ensure that all

data is recorded, modified, or managed according to legal guidelines, with clear documentation of who did what; auditable, or including capabilities to independently verify that the output of the process is logically consistent with the input; transparent, or including capacities to be easily understood in terms of how the technology works and what its implications for the electoral processes are; and sustainable, or including the ability to be repeated without depleting available resources.

Among procedures, the most important are the introduction of a new voting system in the post-electoral period, rather than a pre-electoral one, because this allows more time for feasibility studies, pilot projects, system modifications, and operator training; and the operation of an electronic voting system with the awareness that there are no one-size-fits-all solutions to problems that might occur, and these need to be contextually resolved after broad discussion involving implementers and stakeholders. If electronic voting systems are selected and operated appropriately, with sensitivity to the diversity of voters and the variety of electoral situations, electronic voting has a good chance of becoming the future of voting globally.

Warner, Mark

Virginia's junior Democratic Senator since 2008, Mark Robert Warner has been described as a centrist and one of the fastest rising stars of the Democratic Party. Warner is a multimillionaire who made his money as a venture capitalist in the telecommunications field; he founded the venture capital firm Columbia Capital Corporation. From 2002 to 2006, Warner served as the 69th governor of the Commonwealth of Virginia. He is married to Lisa Colis, who he met in 1984; Warner and Collis have three daughters: Madison, Gillian, and Eliza.

Warner earned a B.A. in political science from George Washington University in 1977; his educational career was notable as he was valedictorian, graduating with a grade point average of 4.0. While in college, he worked on Capitol Hill, in part to pay for his tuition, serving in U.S. Senator Abe Ribicoff's office. Upon graduation, he attended Harvard Law School, attaining his J.D. in 1980; however, Warner has never practiced law. Following Harvard Law, he served as a staff member for U.S. Senator Christopher Dodd. Prior to serving as governor, Warner amassed a fortune as a venture capitalist who organized investor groups to apply for licenses for radio frequencies for mobile phones when the Federal Communications Commission started giving out cellular

licenses. He founded Columbia Capital in 1989, the largest technology venture capital fund in the mid-Atlantic region. Warner was an early investor in several new technology companies that created thousands of private sector jobs. These funds provided Warner the wealth needed to pursue public office. Also in 1989, he managed Democrat Douglas Wilder's successful gubernatorial campaign for Virginia. He then served as chair of Virginia's Democratic Party in 1990.

In 1997, Warner developed and launched the Virginia High Tech Partnership, which helps students from Virginia's five Historically Black Colleges and Universities (HBCU) pursue technology careers through a summer internship and job placement program with more than 75 high-tech businesses. While managing director of Columbia Capital in 2001, he worked with the Virginia Foundation of Independent Colleges to develop Tek.Xam, a four-hour certification assessment that measures computer-technology and problem-solving skills. Meant for liberal arts students to demonstrate their grasp of technology and computer applications, it was designed to provide employers credentials that a college transcript might not show. Tek.Xam tests many broad technology skills, including Web page design, Internet research and evaluation, Internet legal and ethical issues, analyzing and presenting data in a spreadsheet, and creating word processing documents. The test is now extensively used in

colleges and universities and has received endorsement from many corporations.

As a private citizen, Warner helped create the Virginia Health Care Foundation, which has provided health care to more than 600,000 underserved Virginians in areas such as a health safety net, mental health services, medication assistance, and child health insurance outreach. He also launched SeniorNavigator.com, a 501(c)(3) non-profit organization that provides free information about health and aging resources available to Virginians, after his own frustrating experience with the health support system when his mother was diagnosed with Alzheimer's disease. SeniorNavigator links the Internet and a network of volunteers to help older Virginians and their caregivers find answers to medical questions and to identify local resources and services.

Warner conducted an unsuccessful U.S. Senate run in 1996 against long-time incumbent Republican John Warner (no relation). The outcome of the race was closer than expected, with Mark Warner doing well in rural parts of the state, where he sponsored a NASCAR driver and supported gun rights, as well as in Northern Virginia, the tech corridor. He reportedly spent \$10 million on the race, much of it his money. Although a losing effort, the close election provided Mark Warner the boost to run for Virginia's governor five years later.

Governorship

In 2001, Warner was elected governor of Virginia, winning 52.2 percent of the vote over the Republican opponent, former Virginia governor, Mark Earley. Given his Democratic Party affiliation, Warner was assumed to be on the unpopular side of most economic and social issues in conservative Virginia. Instead, he successfully reconnected with rural citizens, focusing on their unemployment rates and pro-gun stances. He organized a "Sportsmen for Warner Group," and a bluegrass song written for him termed Warner "a good ol' boy" who would work for mountain people, "from their coal mines to the still," hailing him as the "hero of the hills." With these efforts, Warner was able to garner a few more percentage points in rural cities and counties, reducing the Republican stronghold in these most conservative part of the state. His victory count also included a

substantial gender gap in Warner's favor (53–39 percent women), and Warner outspent Earley \$19.9 to \$11.5 million. However, Warner's win did nothing to impact the Republicans' strong sweep of House seats, where they captured 64, leaving him with a statehouse controlled by Republicans. Given Warner's victory, though, it demonstrated that a Democratic candidate could successfully run in a conservative, Republican state.

Warner entered the governorship facing a state-wide \$6 billion budget shortfall, but he left office four years later with a budget surplus. With overwhelming GOP majorities in the House and Senate, he worked to overcome bipartisan differences, including naming three Republicans to his cabinet. This bipartisan legacy would become part of his radical centrism, as he called it. His term also suffered several crises, such as an avian flu epidemic, the Washington, D.C., area sniper attacks, and a state-wide drought. The revenue shortfall forced Warner to seek a \$1.4 billion tax increase, and to order severe state government cuts. He also modernized Virginia's entire tax code to promote long-term fiscal integrity and the preservation of core services. These financial measures would result in signature achievements, among many initiatives.

Governor Warner promoted a progressive agenda based in the importance of the information age, with priorities in education, technology, health care, and workforce development. He began a \$12 million fund that allowed broadband to stretch 700 miles through some of the most economically distressed areas of Virginia, beginning to bridge the digital divide. Warner started TechRiders, an innovative program at work that partnered with Virginia churches to teach basic computer skills. He initiated the Virginia Health Care Foundation, which has provided health care to more than 400,000 underserved Virginians in rural and urban areas. Warner's workforce development initiatives added 150,000 jobs by reeducating citizens with insufficient education, most in new technology fields, and in areas hit by manufacturing and tobacco job losses. He also established four regional investment funds (in the Southwest, Southside, Richmond, and Tidewater areas) to attract businesses. He ensured community college affordability, and worked to strengthen public education by making business-like reforms to public schools.

From 2004 to 2005, Warner chaired the National Governors Association, which improved his national profile. He began a leadership political action committee, Forward Together, committed to helping elect individuals focused on bringing commonsense solutions to government by supporting candidates not bound by ideology or agenda. He still serves as its honorary chair. Virginia was rated “the best managed state in the nation” in January 2005, after a two-year study by the Pew Charitable Trust. The same year, *Time* magazine named Warner one of America’s “Five Best Governors,” declaring the Commonwealth the country’s best state for business. In 2006, *Newsweek* named him in the “Who’s Next” issue, and he was featured on the *New York Times Magazine* cover as a bright new Democratic star destined for higher office.

Warner left the governor’s office four years after election (as required by law; in Virginia, there is no second term) with a 70 percent approval rating, despite the tax hike and cuts. He established a budget surplus out of an initial enormous shortfall while creating major investments in K–12 education and college and university systems, increased workforce development, enhanced technology, and cleaned up the Chesapeake Bay. Warner’s name was often floated as a potential candidate for the 2008 presidential race, but in October 2006, he removed his name from contention. Warner was a keynote speaker at the 2008 Democratic Convention that selected Barack Obama.

U.S. Senate

On November 4, 2008, former Governor Warner was elected to the U.S. Senate, defeating former Governor Jim Gilmore with 65 percent of the electorate supporting him (more than 1 million votes). The Senate seat became open when five-term Senator John Warner chose not to seek another term. Warner’s victory was the most lopsided win for a contested seat in 20 years. Warner led the polls from the start, often by a 2–1 margin. Governor Warner was popular due to his exceptional record of bipartisan successes, centrist stances, and fiscal management skills. He outspent Gilmore nearly 10–1. Gilmore’s attacks (primarily on the less expensive Web), tried to cloak Warner as someone who violated his promises for raising taxes while governor. However, Warner’s popularity carried over (and Gilmore had not enjoyed such

popularity during his gubernatorial term), and the push by Barack Obama’s candidacy accelerated the trend toward electing Democrats. Warner also promised to be a radical centrist, working to create bipartisan coalitions. That pledge has remained a hallmark of his time as senator.

Warner serves on the Senate Banking, Budget, Commerce and Intelligence committees. He has become a national leader in efforts to reduce the federal debt, as well as a leader in promoting innovations that will encourage small businesses and startups. Among his initiatives are efforts to improve the lives of military families, including upgrading older military housing and Veterans Administration services to female military veterans. His technology background helped him to bring in several leading technology companies to produce a comprehensive, free plan to correct mismanagement at Arlington National Cemetery. He leads a bipartisan task force focusing on the elimination of waste in the federal bureaucracy. He was part of a bipartisan congressional super committee that was responsible for compromising on cuts topping \$1 trillion under a last-minute deal that proposed to raise the federal debt ceiling proposed in August 2011.

Their efforts failed, leading to the threat of the fiscal cliff (severe cuts to programs and raising taxes) by the end of 2012. Warner voted in favor of the 2010 health care reform bill (Obamacare), and he played a leading role in drafting the Wall Street reform bill that became law in July 2010. He cosponsored the Fair, Accurate, Secure and Timely (FAIR) Voting Act of 2012, which provides incentives to stakeholders who collaborate on election reforms such as flexible voter registration, improved training of election officials, reducing waiting times at polling stations, no-excuse-needed absentee voting, and assistance to voters who do not speak English or those with disabilities.

Perhaps Warner’s most recognized bipartisan activity is his leadership of the Senate’s bipartisan Gang of Six, begun in 2011 to produce a comprehensive plan on the long-term deficit. Three Democrats and three Republicans collaborated to propose a \$3.7 trillion deficit reduction, which included entitlement and spending cuts, along with \$1 trillion in new tax revenue. Their proposal failed to garner enough support in Congress, attributed to a lack of House representative membership, no

party leadership, and Republican unwillingness to consider tax increases. The group (now joined by two other senators, making it the Gang of Eight) continues to meet, and their symbolic value lies in bipartisan attempts to solve the growing debt crisis, even if their proposals are turned away.

From January 2009 to December 2012, Warner missed 32 of 1,157 roll call votes, which is 2.8 percent, slightly more than the median of 2.0 percent among the lifetime records of senators currently serving. Senator Warner announced in November 2012 that he will not seek election as Virginia's governor in 2014, stating that his role is in the Senate.

As of November 2013, Senator Warner had a Twitter account with more than 43,000 followers, an active Facebook page with more than 25,000 "likes," and regularly updates his YouTube page and Flickr photo stream. He has also held Twitter and video town halls.

developing world. Founded by Gary White and actor Matt Damon by merging their organizations in 2009, Water.org uses diverse approaches to addressing water issues by categorizing the population in need into two groups: those who have an income, and those in absolute poverty. Using social media to raise awareness, requiring local participation and decision-making from recipient communities, and facilitating a new focus in microfinance called WaterCredit are three characteristics of Water.org that distinguish it from other NGOs in this sector.

Water.org uses social media to increase public awareness and decrease the distance between donors and local recipients. Even small-time donors can now contribute online and add their voices by sharing the news with friends through online social networks, making Water.org in many ways a grassroots-to-grassroots operation. Donors can also be connected to the communities they are supporting through real-time updates of project progress. Water.org states that its purpose is to be transparent and accountable to both donors and recipient communities. By using social media, Water.org allows even the smallest donors to see where their money is going.

Founders White and Damon have also been active in using media to bring attention to the water and sanitation sector by encouraging everyone to make water and sanitation the main humanitarian focus of the world. They say that they have made it easy, and that donating a voice may be more important than donating money. Voices matter politically because White and Damon also attempt to persuade policymakers to direct more government aid to this sector, and have been critical of the lack of attention given by President Obama.

Water.org's approach to water needs in developing areas are meant to be driven by local participatory efforts and input. Participation is expected at every level of projects. Ownership among the recipient communities is seen as a necessity, and Water.org requires the use of local skills and materials to ensure continued use and sustainability. Having learned from the shortcomings of other organizations over the years, projects are designed to include only technology that is sustainable and repairable by recipient communities.

Recipients are expected to bear some of the cost of projects, either through financial contribution

Water.org

Water.org is a nongovernmental organization (NGO) that focuses on water and sanitation in the

The cofounder of Water.org, Gary White, visits a neighborhood water pump in Mereb-Meatie, Ethiopia, in July 2009. Water.org has facilitated the development of microfinancing focused on water and sanitation. Reducing the time spent acquiring water in the developing world has been found to allow for more entrepreneurial activity and for the repayment of WaterCredit loans.

or physical labor. In addition to these initial contributions, users are required to pay for the new water services to sustain the maintenance needs of equipment. Too much dependency on international organizations can often result in short-lived fixes. The problem returns and goes unaddressed until a new international organization comes along to repeat the process. By requiring local participation and ownership, Water.org believes that individuals and communities will be invested in sustaining these water solutions on their own.

A unique feature of Water.org is its innovative merging of the water and sanitation sector with microfinance. They have distinguished between people who are working and able to sustain themselves and those who are in desperate need and cannot make any contribution to water solutions. The

day-to-day lives of this working group are afflicted by difficult conditions caused by inadequate infrastructure and resources. Accessing water for much of the world's population is a time-consuming and labor-intensive process. Time spent fetching water is time not spent earning income. Building on the assumption that time is valuable to this working population of the developing world, WaterCredit makes small loans available to people who can then solve their water problems.

Water.org is not a bank but a facilitator of a new relationship, turning microfinance institutions on to a new era of water and sanitation. These institutions formerly focused solely on income generating efforts. WaterCredit demonstrates that providing for basic water needs indirectly supports such efforts by eliminating the time-consuming

effort of obtaining water. The time and energy formerly spent on water can be dedicated to employment, often entrepreneurial, thereby enabling economic growth and the repayment of the WaterCredit loans. More money is therefore reserved by Water.org for grants to those who cannot take out loans or afford contributions.

This use of microfinance principles permits Water.org to do more with less in addressing the world's water needs while generating public support through social and political channels. Water.org's objective is to help more people address their water needs by empowering them to solve their water problems in sustainable and participatory ways, and they invite donors to participate in this cause.

We the People

"We the People" is the name given to a section of the White House's official Web site that allows citizens to create and sign electronic petitions. It is White House policy to respond to all petitions that reach 100,000 signatures. The subject matter of submitted petitions varies from serious political concerns to lighthearted forays into popular culture. The page has generated substantial

discussion regarding the role of new media technology in democratic processes. The idea for an online petitioning system came from Macon Phillips, the White House's director of digital strategy. A similar platform had already been in place in the United Kingdom at this time (HM Government e-petitions). Barack Obama's senior advisor, David Plouffe, liked the idea and moved the project forward. We the People officially launched on September 22, 2011. The name of the Web site was taken from the preamble to the U.S. Constitution. The subtitle of the page is "Your Voice in Our Government." Numerous areas of the Web site remind visitors of Barack Obama's commitment to democratic principles such as openness, public trust, transparency, public participation, and collaboration.

The We the People Web site describes its procedures in three steps. First, users are instructed to browse We the People in order to locate petitions that address their policy concerns. Once a user locates a petition relevant to their concerns, they should add their signature. The second step suggests that users should create a petition if they do not see their policy concerns represented in any already existing petitions. The third step places responsibility on the White House for responding to petitions that meet a predetermined signature threshold. Newly created petitions are not searchable until they collect at least 150 signatures in 30 days. The threshold to have a petition addressed by the White House is much higher. Petitions must receive at least 100,000 signatures within 30 days to earn a response from the White House. The subject matter referenced in each petition determines which agency will be assigned the task of responding to it. When the project launched, the threshold for earning a response was originally set at 5,000 signatures, but the ease with which several early petitions reached that mark encouraged officials to increase the threshold to 25,000 on October 3, 2011. The threshold has remained at its current mark of 100,000 since January 16, 2013. As of May 1, 2013, We the People boasted more than 8 million users, 200,000 petitions, and over 13 million signatures.

The content of We the People petitions significantly varies. Marijuana legalization requests are among the most popular petitions at the site. A petition titled "Legalize and Regulate Marijuana

in a Manner Similar to Alcohol,” along with seven similar petitions, earned a response from Gil Kerlikowske, director of the Office of National Drug Control Policy. Kerlikowske opposed the petition, arguing that marijuana use has negative effects on human health. Another petition called for the abolition of the Transportation Security Administration. Numerous petitions filed on behalf of individual states have requested secession from the United States. One petition that has been credited with effectively getting the attention of government officials aims to reverse a law that makes it illegal for cellphone users to unlock their devices in an effort to change service carriers. Some petitions that have fallen roughly in line with President Obama’s agenda include those that seek to reduce gun violence and improve the United States’ immigration system.

We the People has produced a bevy of petitions that focus on issues not typically addressed in mainstream political discussions. In fact, many of these petitions may seem unusual or humorous to some political observers. For instance, when Twinkie, a brand of American snack cakes, was forced to stop production, citizens filed a petition with We the People that sought to nationalize the Twinkie industry so that Americans would not have to live without the popular snack. One of the more peculiar petitions to earn a response from government officials called for the construction of a Death Star—an enormous fictional space station that is capable of destroying planets and was made popular by the film *Star Wars*.

Paul Shawcross, chief of the Science and Space Branch at the White House Office of Management and Budget responded to the petition by noting how expensive the project would be, and reminding citizens that the Obama administration does not support blowing up planets. Shawcross’s response included numerous *Star Wars* references, indicating that he recognized the humor in the petition, and was likely a fan of *Star Wars*. Other lighthearted petitions that garnered media attention sought to create a reality television program starring Vice President Joe Biden, and to create a trillion-dollar coin featuring an image of actor Henry Winkler, famous for his work as the Fonz in *Happy Days*.

We the People has had its share of detractors, many of whom point to frivolous petitions as

evidence that the site is unlikely to generate real political change. Other critics have argued that the site is an attempt by the Obama administration to earn public relations points by appearing to care about citizens’ concerns. Some have found fault with the quality and quantity of the administration’s responses to petitions. Still others have pointed out bugs in the site’s mechanics.

Champions of We the People have observed that it uses new media technologies to make good on American’s constitutional right to “petition the government for a redress of grievances.” Ethicist J. H. Snider has praised We the People for giving political minorities the opportunity to mobilize themselves and place their issues on the public agenda.

Web Mapping and Online Politics

Web mapping refers to the process of collecting, delivering, and sharing geospatial data online utilizing geographic information visualization technologies. While the technologies were not invented purely for political empowerment, in the past decade, Web mapping started to show its potential for influencing politics through facilitating information publicity and sharing, encouraging public participation, and offering platforms

for grassroots activism in both democracies and authoritarian regimes across the globe.

Technologies

In the early 1990s, Web maps were mostly static, which means that the maps were created as picture files (such as JPEG, GIF, TIFF, and PDF). Xerox PARC Map Viewer, developed by Xerox Corporation in 1993, generates GIF images with limited interactive information retrieval features. A map (that is, a picture) will need to be re-delivered every time new information is requested. Today, most Web maps are dynamically created with the help of geographic information systems (GIS), a system designed to capture, manage, and present geographical data. For example, animated Web maps, usually implemented in Flash, Java, or QuickTime, could show changes in a map over time. Dynamic Web mapping can be highly interactive. Google launched its searchable, pannable, and zoomable Google Maps in February 2005. Google Maps heavily relies on JavaScript, a scripting language capable of creating dynamic Web sites. Users can be selective and choose to view the area they are interested in. When users zoom in on a map, there is no need to reload the whole page. Instead, new information will be downloaded from the server and inserted into the page. If data are collected continuously, a real-time map can show the developing pattern of a distributed geographically phenomenon. The “1 million tweet map,” for example, visualizes the number of tweets posted across the world.

The advent of Web 2.0 further complicated the scenario by amplifying the role of the masses in Web mapping. The server-to-user unidirectional map viewing experience is now supplemented by a bidirectional collaboration process in which ordinary users are able to upload information to the server, which in turn makes aggregated data available to others. This is facilitated by the quick spread of mobile devices from which geographic information can be collected, such as smartphones, Internet tablet computers, Wi-Fi-enabled digital cameras, and handheld GPS (global positioning system) navigators, and an explosion of mapping applications such as Google Maps, Bing Maps, MapQuest, OpenStreetMap, and Apple Maps. Individuals with nontechnical backgrounds can not only interact with a map, but also have

personal maps. Using Google Maps API (application programming interface), one can integrate Google Maps into one’s Web site and overlay customized data onto the map.

Another noteworthy trend for Web mapping is the phenomenon of collaborative mapping, making maps with user-generated content. Inspired by the success of Wikipedia, Steve Coast, the founder of OpenStreetMap, began his project by making a neighborhood map with GPS and a laptop computer, and invited more people to join in 2004. Each individual contributed a small piece of map, which was later assembled into a single patchwork. Eventually, this led to the birth of one of the first royalty-free, open source maps of the world through volunteer effort.

Web Mapping and Information Sharing

Maps are good storytelling tools in news media. The emergence of dynamic Web mapping makes maps more interactive and thus informative, better fitting the needs of online news readers in the 21st century. One of the most frequent instances of news media using Web maps concerns the coverage of elections. During the 2012 U.S. presidential election, the *New York Times* published a series of maps tracking the distribution of election votes across the country in real time.

By clicking on different parts of the map, readers could review the breakdowns of vote percentage by states and counties, and the change in vote share compared to the 2008 election. Web maps were also used for covering non-election-related news. Al Jazeera, a media corporation owned by the state of Qatar, has an “Interactive” section on its Web site, featuring political news utilizing geographic visualization techniques. One recent project tracks the number of social media posts from Israel and Gaza during violent times in 2012, and another shows the death toll by province during the uprising against President Bashar al-Assad’s rule in Syria.

Other than the news media, governments around the world learned to use Web mapping for more effective communication with the public. The Obama administration recently posted on the White House Web site an interactive map visualizing more than 10,000 federal government-owned properties that are designated as excess. The urgency and the scale of the issue was well

communicated with the help of a map. In the United Kingdom (UK), a radioactive waste inventory was hosted on the Web site of the Nuclear Decommissioning Authority (NDA). Using maps, comprehensive and up-to-date information on radioactive waste in the country is presented to the public.

Web Mapping and Public Participation

In addition to catering to the informational needs of the public, Web mapping offers a special means to public participation in community planning and decision-making processes. In this context, the technology has been closely associated with the notion of cyberdemocracy. The ability of the public to effectively participate in neighborhood planning processes largely depends on the answers to three questions: (1) whether the public can have access to detailed planning information; (2) whether the information delivered is easily digestible; and (3) whether communication between different stakeholders is free and equal. Well-designed Web public participation GIS system (PPGIS) can substantially reduce the ambiguity in communicating geographic information. Community members may make spatial searches and queries, pinpoint a location on a map, directly interact with spatial objects on a map, build scenarios with online editing functions, evaluate different plans, and voice their opinions.

The UK has made important headway in utilizing the tool. The Slaithwaite Public Participation Geographic Information System is an early effort made to involve people in local planning and decision making for the village of Slaithwaite in West Yorkshire, England. The site was first developed in 1998, but was rehashed in 2003. The main interface of the system is composed of two components: a dynamic map implemented in Java, and a text input box for user communication. Users can move the cursor over the objects in the map (e.g., buildings, roads, railway lines, rivers, and playing fields), highlight the object of interest, and submit their ideas and comments using the text input box. Other examples of PPGIS include deciding the location of woodland regeneration projects, wind farms, and models of urban change. PPGIS provides a tangible means to engage citizens in the consultation process to build consensus for planning.

Web Mapping and Grassroots Activism

In contrast with the public participation GIS model, which was more or less promoted by local or regional government bodies through a top-down approach, the phenomenon of crowdsourced mapping is more grassroots-oriented. Crowdsourcing is to take a job usually performed by a designated agent and to outsource it to an undefined large group of people, according to Jeff Howe, the contributing editor at *Wired Magazine* who coined the term. Although different from PPGIS, crowdsourced mapping also holds potential for a vibrant citizenship and democracy.

One trailblazer in the development of crowdsourced maps is Ushahidi, a nonprofit Kenyan open source software company focusing on interactive Web mapping. In January 2008, while government's control of traditional news media prevented timely coverage of postelection riots and violence that broke out in Kenya, a prominent local blogger, Ory Okolloh, proposed to build a Google map showing the locations where violence was witnessed (Ushahidi, in Swahili, means "testimony" or "witness"). Considering that Internet penetration in Kenya was below 10 percent at the time, software developers turned to mobile phones as a solution. Ushahidi.com was created as a platform allowing people with a mobile phone to send SMS text messages to a central database. The information is posted onto a live map once it has been verified.

The power of grassroots Web mapping is by no means limited to reporting and broadcasting violence in Kenya but is widely used across the world for different causes such as crime prevention, environmental protection, human rights enhancement, and disaster relief. However, not all grassroots Web mapping is crowdsourced. A broader term to describe the use of Web maps to garner attention on social or political issues is *maptivism*, the combination of mapping and activism. Using Google maps API, a Tunisian human rights activist blogger, Sami ben Gharbia, put together a prison map when such information was kept secret by the government. The "Harass-Map" from Egypt mapped the location of women protesters who were harassed or attacked in the streets during the country's protests through SMS reporting. Jeff Warren and volunteers from the United States used camera-equipped balloons and

Members of the grassroots mapping group mapping the 2010 BP oil spill by releasing a camera-equipped balloon in the Chandeleur Islands of Louisiana to take aerial shots of the spill.

kites to collect aerial photographs of the Gulf Coast to track the spread of the 2010 BP oil spill. In China, a blogger named Guo Baofeng maintains a “China Pollution Map” that documents nationwide pollution instances by aggregating information from both news coverage and individual witnesses. Crowdsourced mapping also demonstrated its power in disaster relief after the 2010 Haiti earthquake. In 2011, the United Nations (UN) held an expert meeting on crowdsourced mapping and decided to establish the UN Platform for Space-based Information for Disaster Management and Emergency Response (UN-SPIDER). Finally, big corporations also use mapping to support causes. Google started a campaign in late 2012 to promote a free and open Internet by soliciting Internet users to sign a pledge letter and express their thoughts on the issue of Internet governance. Whenever an individual submitted his or her pledge, a colored circle would be added onto a world map in real time. A map filled with circles demonstrated that Google had amassed a substantial amount of support from Internet users around the world.

Criticisms and Concerns

Despite the influence of Web mapping on politics, Web mapping does receive criticism of various types. Among others, three concerns seem to be most prominent. First, Web GIS has primarily been criticized as an elitist technology because there are many people not connected to the Internet. Even for those who are online, the voices of a few will dominate cyberspace. Second, many Web maps, in particular grassroots maps, are of poor quality. Information presented in the maps is not accurate enough. The third issue concerns privacy. When massive amounts of user-generated information is presented in Web mapping through location-based services, the personal information of individuals is sometimes made publicly available, thus putting privacy in peril.

Web Metrics

Web metrics are the tools for collection, measurement, and analysis of Web data. Metrics are often provided in the form of statistical data about an organization’s performance on the Internet, including Web usage and patterns, usability of

the online platform, individual transactions, user supplied data, and overall Web site performance. Web metrics, also known as Web analytics, allow one to produce numerical reports of Internet usage, with the purpose of understanding online behavior of target publics and optimizing Web content and Web site effectiveness. Before the invention of Web analytics, Web site design was mostly seen as a creative process, and its structure and organization were solely based on the subjective judgments of creative minds. Today, metric data allow analysts to determine usage patterns and trends over time, identify which sections and features of a Web site users most frequently visit and consider most useful, and discover what type of information is most often sought and accessed. Web metrics also measure how much time each visitor spends on a page and record what path he or she takes to find that information. For example, using metric data, a nonprofit organization may want to optimize its Web site structure and content to increase donations.

Web metrics operate with the data collected by software that tracks and records mouse clicks and information requests (e.g., uploads, downloads, and picture or video views) from browsers. The initiation of Web usage data collection requires the embedding of a computer code into each of the Web pages that need to be analyzed. The data then is collected using either server log files or via page tagging, producing Web site traffic reports, often with geographical locations of visitors. The data are stored on remote servers, and theoretically do not contain user identifiable information. The data can then be accessed and used for business and market research, effectiveness assessment, and research on users, user habits, and traffic trends.

Units

Metrics for Web analytics usually employ three common units of measurement: counts, ratios, and key performance indicators (KPI). Count is the most basic unit of measurement that records a simple number, such as number of visits/sessions, unique visits, Web site hits and click throughs, pageviews, “likes,” downloads, and visit duration. Ratio is a more advanced unit of measurement, comprised of a count divided by a count, or a count divided by a ratio. For example, page

views per visit are measured as the number of page views divided by number of visits within a certain period of time. Other ratio-based metrics include page exit ratio, bounce rate, and click-through rate.

Strategy

However, these units of measurements remain just numbers if they are not strategically used. Web metrics provide little knowledge and value to an organization if they are not tied to its strategic goals. KPIs are considered the most advanced Web metrics because they are infused with an overall organizational strategy. KPIs are quantifiable (can be both a count and a ratio) measures that allow one to define, evaluate, and track progress toward organizational goals. Using simple outcome indicators, KPI metrics break down complex measures to help those not involved with Web site operations to analyze Web site performance and evaluate whether and how the Web site facilitates the achievement of organizational goals. In this sense, KPIs make Web metrics a strategic tool that drives organizational development.

The choice of key performance indicators depends on the industry and purpose of the Web site. However, there are a number of KPIs that provide good intelligence across the board. For example, the content-focused Web sites of organizations such as MoveOn.org have the goal of keeping visitors longer on the Web site and making them come back. To help the organization achieve this goal, the use of KPIs such as traffic concentration, single access ratio, depth of visits, returning visitors, new visitor percentage, page/content depth, and top internal search phrases can be beneficial.

Traffic concentration KPI allows one to determine which areas of the Web site generate the most interest. Single-access ratio measures the effectiveness of landing pages, when people find the desired content without entering the homepage. Depth of visit measures engagement and level of interest in the content provided by dividing page views by visits—the more engaged visitors are, the more pages are viewed. Page/content depth measures interest in certain content areas over time, and is critical in determining functionality and navigational effectiveness of the most visited sections of the Web site. Lengths of visit

measures how quickly and easy it is for users to find the information they are looking for. Top internal search phrases provide insight for identifying areas that may require better navigation or more content to meet customer demands.

When a KPI is appropriately chosen, it is capable of revealing a meaningful change in user activity and Web site performance in a given period, such as data on landing pages (where people come in), exit pages (where people leave from), and content drilldown (which site sections do best). For example, a sudden spike in traffic, when put in context of the event that caused it, provides ideas on potentially effective strategies for driving traffic to the organization's Web site. If a new blog post causes an increase in traffic, then blog posts have to be regularly updated, and the content should be engaging in order to maintain the traffic rate.

Web 2.0

Web 2.0, also called the participatory Web, refers to a conceptualization of the Internet as a

platform in which users are the primary engineers of information. Through Web 2.0 technologies, individuals, many of whom have no specialized training, are able to write, develop, and create videos, applications, and Web sites. Web 2.0 most often refers to rapidly expanding and evolving platforms such as social networking sites, user-contributed sites, self-publishing platforms, and social bookmarking sites. These platforms may include social networking, wikis, blogs, podcasts, RSS (really simple syndication) feeds, and other media sharing sites that are characterized by masses of users participating in content creation.

Web 2.0 has ushered in dynamic changes in Internet content creation and has capitalized on collaboration, tagging (assigning a nonhierarchical keyword or term to a piece of information), and viral marketing. These characteristics have substantially impacted political communication, campaigns, and governance by helping to create an interactive, content-rich architecture of online participation and by delivering a richer and more user-focused political experience.

Attributes of Web 2.0

There are many attributes of Web 2.0 that add to its participatory nature. Web 2.0 makes it possible to combine data and information from various sources and to build content through the collaborative use of online spaces, thus changing the process of creation and distribution in online environments. A focus on collaboration allows interested parties to add value to the applications that they use and to create dynamic content and metadata.

Web 2.0 has changed the structure of the Web by allowing users to generate and add new content and sites, and to create fluidity in categorizations through hyperlinking and tagging. These activities allow for multiple overlapping associations, rather than rigid categorizations, and permit other users to alter the structure of the Internet by discovering, commenting, editing, and linking to content.

Through the expansion of Web 2.0, a social Web has emerged, creating a fundamental expansion in the ways in which people communicate. Through the use of online tools, users interact to share perspectives, opinions, thoughts, and experiences. This shift has also allowed users to

become prosumers of information; users have become active participants in the development of content, and are no longer simply passive viewers of Web site content.

Web 2.0 and Politics

Web 2.0 has significantly impacted political communication, campaigns, and governance. This environment has changed the traditional top-down direction of political communication. Political parties, campaigns, and politicians are no longer the primary creators and disseminators of political messages; Web 2.0 allows the public to also participate in the creation and distribution of political information. This shift has created communication structures that are more horizontal and focused on engaging and building relationships with constituents and potential voters. In the Web 2.0 environment, it has become requisite for parties, candidates, and government officials to have profiles on multiple platforms in order to facilitate communication with the public and engage voters.

Web 2.0 has fundamentally altered political fundraising and mobilizing efforts. These platforms have created new avenues to reach targeted groups for financial and volunteer support. Campaigns have been able to connect with supporters who have historically not responded well to offline methods of fundraising and mobilizing, such as those in younger demographics. Leveraging the Web 2.0 environment for these purposes has allowed campaigns to raise vast sums of money in \$5–\$10 increments, to organize volunteers, and to gain access to specific groups of supporters.

Web 2.0 has altered the distribution of inexpensively produced, targeted political advertisements, and has created emphasis on virality (the ability for videos to go viral). Via Web 2.0, campaigns can distribute agenda-driven advertisements and measure, almost in real time, the success of campaign messages; messages that do not achieve virality can be quickly and cheaply altered and redistributed. Virality, however, can positively and negatively impact campaigns. Web 2.0 supports an active audience, where users seek out information and videos to share and repost. This can significantly increase the circulation of campaign messages, but because many

online political messages are not engineered by campaigns, virality can have negative results.

Web 2.0 has also impacted how elected officials conduct business. Government officials use Web 2.0 platforms to inform constituents, engage in policy discussion, and provide rebuttals to negative or inaccurate information. In the Web 2.0 environment, constituents expect elected officials to maintain a level of visibility and transparency not previously expected through other communication mediums.

Concerns Regarding Web 2.0 and Politics

The evolving nature of the Web 2.0 environment has also raised some concerns, especially when considering its impact on politics. The user-generated nature provides the opportunity for anyone to share and place value on their opinions, to distribute potentially uninformed political commentary, and to conceal biases or hidden agendas.

Additionally, the environment has heightened the entertainment value of politics and allowed individuals with limited knowledge and credentials to participate in the creation and dissemination of political information. These factors can create collateral damage for parties, politicians, and campaigns if they are not able to quickly and effectively rectify and correct inaccurate viral messages. Concerns regarding the erosion, redefinition, or outright loss of citizen privacy are an increasingly important issue because the harvesting of social media data and metadata without citizen knowledge or permission has become increasingly routine. High-speed, high-volume cross-tabulation software can aggregate that information into a comprehensive and often deeply personal digital profile that is useful to both commercial and political interests, but it is often invasive to the people on whom it is collected.

Conclusion

Web 2.0 has significantly changed the ways in which individuals interact with the Internet in general, and with politics specifically. As technology continues to evolve, new Web 2.0 tools will provide users with new and emerging ways to engage with and understand politics.

Weibo

Weibo is the Chinese term for “microblog.” *Wei* is the literal translation of “micro,” whereas *bo* comes from the abbreviation of *bo-ke*, a phonetic translation of “blog.” Broadly speaking, weibo refers to a host of Chinese social media platforms and applications bearing technical similarities to their American counterpart Twitter, which has been blocked by Chinese authorities since 2009. Because Sina (a Chinese online media company) takes the lion's share of the market, “weibo” sometimes specifically refers to Sina Weibo.

As of December 2012, there were a total of 309 million people, about 54.7 percent of all Chinese Internet users, using weibo services. Early microblogging services in China can be traced back to 2007, when a group of domestic sites such as Fanfou, Jiwai, Digu, and Zuosa quickly gained popularity. Fanfou became the most influential site when its users exceeded one million in 2009. However, immediately after the July 2009 Urumqi riots (a series of violent ethnic conflicts between Han Chinese and Uighurs), the government blocked Twitter, Facebook, and two foreign-based social media services, and shut down most

domestic weibo services, including Fanfou, Digu, and Jiwai.

The demise of small domestic microblogging sites paved the way for Internet giants' decision to fill a government-manufactured void. At a time when microblogs sounded sensitive to Chinese authorities, Sina took a daring move and launched its Sina Weibo in August 2009. Sohu, NetEase, and Tencent followed suit in early 2010. The current weibo market is dominated by three NASDAQ-listed Web portal companies: Sina, Sohu, and Netease, along with Tencent, known for its instant messenger service QQ. According to a recent blue paper from Data Center of China Internet, the penetration rates (number of users divided by all weibo users) of Sina, Tencent, NetEase and Sohu's weibo services are 87.7, 84.7, 56.1, and 35.6 percent, respectively.

The basic functions of weibo resemble those of Twitter. Each weibo post is usually allowed to contain 140 Chinese characters. Users can choose to make a post publicly visible, or restrict the post to a small group of selected followers. Users may subscribe to other users' posts (“follow” them) so that real-time updates will appear in the follower's timeline. The follower-followee relationship does not have to be reciprocal. Users can address a specific topic by using hashtags, words or phrases bracketed by two “#” signs (different from Twitter's single “#” hashtags), use the “@” sign followed by a username to mention other users, and repost a message from another user and share the content with their followers (i.e., retweeting or forwarding).

Starting out as Twitter clones, Chinese weibo service providers added a variety of features to their products. The most common add-on functions are that users can upload images, graphical emoticons, and videos in their posts; users can initiate customized opinion polls; users can “like” or archive a post; users can directly comment on a post, formulating a threaded discussion, as in online discussion forums; and users are given symbolic rewards, consisting of “medals of honor” to encourage frequent and active use of weibo services. To compete with Sina, the dominant player in the market, unique weibo features were developed by Sina's major rivals. For instance, Tencent integrated its weibo service with its QQ messenger to entice more users,

NetEase expands the length of a post to 163 characters, and Sohu does not place any word limitation on its weibo posts. As a result of these innovations, the user interfaces of Chinese weibo are much more complicated than that of Twitter, and functionally, weibo is akin to a hybrid of Twitter and Facebook.

Censorship of weibo is severe and prevalent. Chinese authorities use various means at different levels to ensure that the new technology will not threaten their authoritative rule. Researchers from Carnegie Mellon University found an overall message deletion rate of 16.25 percent on Sina Weibo. The most commonly seen weibo censorship techniques are automated keyword filtering, manual deleting, active monitoring of selected users, and account suspension/deactivation. Filtering algorithms can detect blacklisted keywords contained in a submitted post, and users will be prompted with a message like “Sorry, the content violates the rules of Sina Weibo or relevant regulations and policies. The system cannot process your specified operation. If you need help, please contact our customer service staff.” To survive in a regime with harsh Internet controls, almost all weibo companies have to comply with government request and employ censors. Manual checking is needed when automatic keyword filtering becomes futile. When post hoc censorship happens, users will receive a system notification such as “Sorry, your post has been blocked/deleted by system administrator. This post is not suitable for being made public.”

Weibo accounts of selected dissidents, reporters, activists, and opinion leaders with a large amount of followers can be actively monitored. If serious or continuous inappropriate expression is noticed, users may face account suspension, account deactivation, or even detention. On March 31, 2012, the commenting function of Sina and Tencent weibos were suspended when rumors about Bo Xilai and Wang Lijun’s political scandal ran rampant on weibo. In addition to these measures, the government implemented a weibo real-name-registration system in major cities on March 16, 2012. To be able to post content, users need to provide their real names and national identification numbers or mobile phone numbers to service providers, however, their screen names can be different from their real names.

Despite heavy-handed censorship from the government, the rapid growth of weibo use has led to the liberalization of public discourse and has provided Chinese people new venues for political advocacy. Chinese people use weibo to expose corrupted officials, find abducted children’s parents, run for the local People’s Congress, and discuss breaking news. To a limited extent, weibo has pushed the Chinese government to respond to public opinion.

Weiner, Anthony

Anthony Weiner became embroiled in scandal in 2011 when he used Twitter to send a sexual photograph of himself to a young woman from Seattle. When claims were first made that the photograph was sent by Weiner, he said that his account had been hacked and he had not taken or sent the picture. However, after a few days of denial, he chose to come clean and admitted to the error in judgment. Further, he acknowledged that this was not the first time that he had distributed explicit messages or photographs (including numerous times after his marriage).

He stated that there was never a physical relationship with any of the online women. While he

initially fought off calls seeking his resignation, he ultimately resigned on June 23, 2011.

Weiner will long be remembered for utilizing poor judgment and for not correctly navigating social media when he made the photograph retrievable by individuals other than the intended recipient. The Weiner scandal has opened the doors to new questions about what constitutes sex (after all, Weiner did more than President Jimmy Carter's lusting in one's heart, but less than the activities of President Bill Clinton) and further questions about the blurring line between public and private life for politicians.

The transgression of most notoriety occurred on May 27, when Weiner sent a photograph of himself aroused in boxer briefs to college students in Seattle. What made the error noticeable to the general public was that he sent a link to the photograph (hosted by yfrog). While the link only remained live and available on his Twitter account for a few minutes, that was long enough for another Twitter user to capture a screen shot of the image and forward it on to well-known conservative blogger Andrew Breitbart, who then shared it with the world.

Initially, Weiner opted to deny everything about the photo, and instead claimed that a hacker had created the link. He claimed that the image was not even of him—instead saying that someone had doctored another photograph of him. Unlike most elected officials in a similar situation, Weiner opted to not ask the FBI to investigate the alleged hack.

A few days later, Breitbart located and shared a second picture of Weiner (shirtless this time) that was sent to a young woman in Texas. She later claimed that she had also received additional photographs from the Democratic congressman that could be considered sexually graphic. With the evidence mounting, Weiner took to the press and announced that, "I have not been honest with myself, my family, my constituents, my friends and supporters, and the media... to be clear, the picture was of me, and I sent it...[I] engaged in several inappropriate conversations conducted over Twitter, Facebook, e-mail and occasionally on the phone...[and I exchanged] messages and photos of an explicit nature with about six women over the last three years." While he had come clean, he claimed publicly

Former Congressman Anthony Weiner at New York City's Gay Pride march in June 2009 before a series of revelations of sexting, especially on Twitter, became public.

that he still had the support of his wife, Huma Abedin, who, ironically, had been an aide to Hillary Clinton. Adding to the irony was the fact that former President Bill Clinton had officiated his wedding.

History of Problems

For those who had followed Weiner's career, these allegations and admissions were not surprising. Prior to being married, the congressman was well known for his dating exploits throughout New York City. He had lived the life of a playboy, and now was facing serious consequences, both professionally and personally. Even after his admission, he was hounded by the media for details of previous transgressions—including a sexting relationship with a woman in Nevada. The media angered both Weiner and Breitbart throughout

the entire ordeal. For Breitbart, the major media anger was raised in early June when he appeared on a Sirius XM radio show and showed the hosts a photograph of what he claimed were Weiner's genitalia. Unknown to Breitbart, a camera had been set up in the studio, and it was used to capture a shot of Breitbart's screen, allowing the radio hosts to publish the alleged picture on numerous social media sites, without Breitbart's permission. Given his previous admissions, this particular incident did little to elicit any response from Weiner or his team.

What seemed to upset Weiner the most was the regular publishing of information about the identities of his social media contacts. In an acknowledgement of the trouble he had caused, he seemed to show remorse for causing the media frenzy around these women. First, Lisa Weiss (a casino employee from Las Vegas) was relentlessly hounded by the media.

She was followed by Ginger Lee (an actress in pornographic films). Lee went as far as to have a press conference in an effort to end the media circus, and disclosed that Weiner had previously told her to just be quiet, and that the scandal would quickly disappear. Not all of Weiner's online flings were as opposed to media attention as Weiss and Lee, however. Traci Nobles, a high school cheerleading coach, went on a national media tour (including a stop at the *Today Show*) and published a book about her relationship with Weiner.

Resignation

The political battle for Weiner gained traction on June 6, when Nancy Pelosi (the top-ranking Democrat in the House of Representatives) asked the House Ethics Committee to open an investigation into whether Weiner was in violation of any rules. The media had begun reporting that one of the now-famous Weiner photographs appeared to have been taken in the House of Representatives gymnasium, which could possibly equate to a misuse of congressional resources. Both Democrats and Republicans were calling for Weiner to resign from the House to protect the body from unnecessary time spent discussing his personal life while the nation was still at a critical point on numerous policy discussions. Rather than resign immediately, Weiner first responded by taking

an approved short leave of absence in order to receive professional treatment for his behavior.

While other members of Congress were fairly uniform in looking for Weiner to remove himself from Congress, New York City residents (and his constituents) were not nearly as decided in their thinking. Two surveys conducted on June 6 showed differing results. The first poll suggested that over half of respondents believed that Weiner should resign his spot, whereas a second poll said that 46 percent of New York City residents felt that the congressman should resign. A follow-up poll three days later and consisting of only respondents from his congressional district showed that more than half wanted him to remain in office—demonstrating again American favoritism toward their Congressman. By June 13, the polls seemed less relevant. First, President Obama strongly suggested that Weiner should resign, for the good of the institution, country, and party. Three days later, Weiner agreed. On June 20, he provided his formal resignation letter to the House, and was out of Washington, D.C., just a day later.

While Weiner was out of the House, he was not out of politics for long. On May 22, 2013, he announced a bid for the Democratic nomination for mayor of New York City. Originally, he was viewed as a strong favorite in a field that included Bill de Blasio, William Thompson, John Liu, and Christine Quinn. Yet his past seemingly became his future when it became known that he had again been exchanging inappropriate messages via sexting under the alias Carlos Danger. This time it was with a 22-year-old woman and he admitted that it had continued after he left Congress. In all, he admitted to continue to sext with three women after the initial scandal broke. Weiner refused to drop out of the race, however, despite experiencing a 20-point drop in the polls. By the time all was said and done, Weiner finished fifth in the primary, receiving less than 5 percent of the votes cast. Weiner showed that old habits die-hard.

Conclusion

Anthony Weiner will go down in the history books as a warning to others. Prior to his scandal, there were no national-level sexting issues. Now, the country has shown its feelings and opinions toward such activities by elected officials. Once a

Democratic politician with a promising political future, Weiner will forever be known as the perpetrator of yet another famous scandal in American political history.

West, Allen

Allen West is a former Republican member of Congress who represented Florida's 22nd District from 2010 to 2012. Although he served only one term in Congress, West gained a national profile as a spokesperson for the Tea Party movement. While in office, he was a frequent guest on TV and radio political talk shows, as well as a prolific user of social media. West was born in Atlanta, Georgia, in 1961. He earned his undergraduate degree from the University of Tennessee and joined the military in 1982. West served in Kuwait during the Persian Gulf War, and then returned to the United States to work as a ROTC instructor at Kansas State University. By 2002, he had achieved the rank of lieutenant colonel, and he deployed to Iraq, serving from 2002 until 2004.

West received a master's degree in political science from Kansas State University, as well as a master's degree in military arts and sciences from the U.S. Army Command and General Staff College. He is married and has two children.

West earned many honors during his 22-year military career, including a Bronze Star and an Army Commendation Medal. In 2003, however, he was disciplined after he participated in the interrogation of an Iraqi police officer. In an attempt to elicit information about a planned attack, West fired a gun near the Iraqi's head. As a result, West was charged with violations of the Uniform Code of Military Justice and was eventually fined \$5,000; he was allowed to retire with honor in 2004. Despite the punishment, many on the right supported West's actions, with 95 members of Congress writing a letter to the secretary of the U.S. Army commending him. Conservative activists also succeeded in raising enough funds to cover his legal defense, and the conservative *Front-Page Magazine* named him "Man of the Year." After retiring from the military, West moved to South Florida and worked as a high school social studies teacher before going to Afghanistan to work as a private contractor. West, who did not register to vote until retiring from the military, made his first foray into politics in 2008, running in Florida's District 22 against Democratic incumbent Ron Klein. West lagged behind his opponent in fundraising, raising only \$585,000 compared to Klein's \$4 million. West lost the election by a margin of more than nine points.

2010 Campaign

In the 2010 midterm election, West again challenged Klein. This time, however, West benefited from the wave of Tea Party enthusiasm. West launched his campaign in a video posted on YouTube. The video, titled *The Revolution*, showed West speaking to a 2009 Tea Party meeting in Ft. Lauderdale. Using allusions from the Revolutionary War, he implored his supporters to "get your musket, fix your bayonet and charge into the ranks," to stand up to the Obama administration. The video quickly garnered a million views, and triggered a flood of fundraising dollars. The largely unknown West gained further prominence after his February 2010 speech at the Conservative Political Action Committee. In the speech,

West emphasized his military service, and charged that the president and congressional Democrats were attempting to implement Marxist policies.

This speech garnered West several high-profile endorsements; former vice presidential candidate Sarah Palin endorsed him on her Facebook page, and former College Football Coach Lou Holtz made a YouTube video supporting West. Because of his growing profile, during this campaign, West outpaced Klein's fundraising, with the Republican challenger raising \$6.5 million, compared to Klein's \$3.7 million. West won the election with 54 percent of the vote, compared to 46 percent for Klein. The election made West the first African American since Reconstruction to represent Florida in Congress. Moreover, West and South Carolina's Tim Scott became the first African American Republicans in Congress since 2003.

Congressional Career: 2011 to 2013

Once in Congress, West was assigned to the Armed Services Committee and the Small Business Committee. West also made headlines by joining both the Tea Party Caucus and Democratic-dominated Congressional Black Caucus. According to Govtrack.us, during his term, West sponsored 11 bills, none of which became law. He cosponsored 313 pieces of legislation. An analysis of his voting behavior showed that he tended to vote along party lines, voting with other Republicans 93 percent of the time. During his term, West was a frequent guest on talk radio and television, especially Fox News, where he was interviewed 17 times while in office. West often garnered headlines for his controversial remarks targeted at Democrats. For instance, in an August 2011 appearance on the *O'Reilly Factor*, he accused Democrats of shortchanging black voters and running a "21st-century plantation." He compared himself to a "modern-day Harriet Tubman," who could lead them to the GOP. Earlier, in April 2011, when appearing on the conservative radio program the *Laura Ingraham Show*, West argued that Obama was behaving like a "low-level socialist agitator." Later, in December 2011, when asked about a poll unfavorable to Republicans, West told a reporter "if Joseph Goebbels was around, he'd be very proud of the Democrat Party because they have an incredible propaganda machine."

Democratic Members of Congress were also a frequent target for West. He engaged a public feud with Debbie Wasserman Schultz, a fellow representative from Florida. The dispute dated to June 2010, when Wasserman Schultz organized a protest outside of West's campaign office, objecting to his affiliation with a biker magazine. Subsequently, in July of 2011, Wasserman Schultz made comments on the House floor criticizing West's support of a bill containing Medicare cuts. In response, West wrote an e-mail to the congresswoman, stating that she was "the most vile, unprofessional and despicable member of the U.S. House of Representatives." The e-mail, which was copied to Minority Leader Nancy Pelosi and House Majority Leader Eric Cantor, concluded by asserting that Wasserman Schultz was "not a Lady." The e-mail was subsequently obtained by the Web site Politico, and circulated widely on conservative blogs.

In addition, during a January 2012 appearance on *The Shalom Show*, West criticized Michigan Representative Keith Ellison, a fellow member of the Congressional Black Caucus. West charged that Ellison, who is a Muslim, represented "the antithesis of the principles upon which this country was established." West stood by this comment in a Facebook posting, noting that he was referring to Ellison's association with the Council on American Islamic Relations (CAIR).

He made another controversial remark in April 2012, during his re-election campaign. At a town hall meeting, West told the audience that there were "78 to 81 members of the Democrat Party who are members of the Communist Party." After video of the statement circulated on the Internet, West took to Facebook to defend his comments. He noted that he was referring to the House Progressive Caucus, who he argued endorsed a Marxist economic view.

In addition to his media appearances, West also used social media to bolster his national profile. He was especially active on Twitter, with nearly 40,000 followers during his term. In February 2012, OhMyGov.com, a Web site that tracks social media usage, ranked West as the number one "most engaged Tweeter" in Congress. Although he typically sent out only one or two tweets per day, West had the highest retweet rate, averaging 112 retweets per tweet.

Former Congressman Allen West raised his profile with a February 2010 speech at the Conservative Political Action Committee (CPAC) of Florida. He is shown here at CPAC 2011 in Washington, D.C., on February 12, 2011.

2012 Election

Because of redistricting from the 2010 census, West's district was redrawn; the new district incorporated more Democratic-leaning areas, making his re-election unlikely. Subsequently, West decided to switch districts, running in the nearby 18th District. His Democratic opponent was 29-year-old political newcomer Patrick Murphy, a former Republican who worked in his family's construction business. National Democrats indicated that defeating West was a priority, with Representative Steve Israel, the chairman of the Democratic Congressional Campaign Committee, arguing that the defeat of West would constitute a serious blow to the Tea Party movement. Murphy, a little known candidate who initially trailed in the polls, focused his campaign on West's past statements, attempting to paint him as divisive and unproductive. West characterized Murphy as inexperienced and elitist. His campaign released

an ad titled *Decide*, which went viral, quickly garnering more than 250,000 views on YouTube. The ad highlighted Murphy's 2003 arrest for public intoxication, and contrasted this with West's actions in 2003, as he prepared to deploy to Iraq.

The race was one of the most expensive House races in the cycle, with West vastly outperforming his opponent in fundraising. West raised \$19.3 million, compared to Murphy's \$9.7 million. Approximately 60 percent of West's donations came from outside of Florida, compared to 27 percent of Murphy's donations. West's national profile was also demonstrated by the fact that he received donations of at least \$1,000 from all 50 states. During the campaign, West spent \$7.4 million on media, and a key component of his media strategy was his online presence. During the election cycle, OhMyGov.com ranked him in the top five in social media usage among all the 2012 candidates. In August 2012, West had 190,000 Facebook fans. He had a similarly strong presence on Twitter, with 83,000 followers.

West's campaign used social media to promote its message and turn out supporters at the polls. For example, West's official Facebook page featured an app that allowed supporters to create customized bumper stickers and yard signs. The Facebook page was frequently updated, with posts regularly receiving more than 1,000 "likes" and hundreds of shares. In addition, the West Campaign used a separate Twitter feed, @ElectAllenWest, to remind supporters to vote. The feed, which had more than 13,000 followers, also featured links to video clips of voters explaining their decision to vote for West. Supporters of West were also active in social media. The Web site and Facebook page Allen West Republic was started in 2011; according to its founder, the Facebook page received between 65,000 to 1.5 million page views per week. Another Facebook page, Allen West for President, had 9,000 "likes" in August 2012, and frequently posted clips of West's speeches and media appearances.

Despite West's fundraising advantage, on election night, the results showed that Murphy had won the election by a margin of approximately 2,500 votes; this was less than 1 percent of all votes cast. West, however, refused to concede, asserting that some ballots from early voting in St. Lucie County may have been erroneously double

counted. A subsequent recount, however, increased Murphy's lead, and West decided to abandon any further legal challenges. West eventually conceded the election on November 20. In a Facebook post that morning, he informed followers, "I will take no further action to contest this election."

Career After Congress

After leaving Congress, West continued to be a prominent spokesperson for the Tea Party. In January 2013, he accepted a position with PJTV, an offshoot of the conservative Pj Media Web site. West was hired to be director of next generation programming; in this capacity, he participated in creating Internet TV episodes about contemporary political issues such as taxes, patriotism, and terrorism. Subsequently, in May 2013, Fox News hired him as a contributor. In addition to his media appearances, West continued his active social media presence. Although he initially lost Facebook followers after his defeat, by late April 2013, these numbers had rebounded, and he had more than 314,000 "likes." He experienced similar growth on Twitter, with more than 151,000 followers in May 2013. As a result of this growth, in May 2013, OhMyGov.com found that among all the 2012 election candidates, West was still ranked number three in social media fans. This included a ranking of number six in Twitter mentions, as well as a ranking of number one in Facebook "likes."

West's use of social media caused controversy in February 2013, when he used his Facebook page to chastise Florida Atlantic University students; he alleged that they were harassing his wife, a member of the board of trustees. In the post, he warned the protesters to stop contacting his wife, or they would "face me, the side of me that you do not want to see." In late May 2013, West indicated that he was interested in returning to politics, possibly in 2016. His political action committee, the Allen West Guardian Fund, exceeded its fundraising goal, raising \$479,000 in the first quarter of 2013. The PAC focuses on supporting minority Republicans and military veterans who are running for Congress.

West Wing Week

When Barack Obama became president, Americans knew the country would experience change. He had utilized social media in a way never seen before in American politics during his presidential campaign, and promised a new level of transparency never experienced before. During the second year of his first term (in April 2010), the Obama White House released the first episode of *West Wing Week*. This online video series was initially created by the first White House videographer in history (and new media road director) Arun Chaudhary before he left and was replaced by Adam Garber. The series is narrated by Joshua Earnest, Obama's deputy press secretary. To this day, the White House has yet to release information about the cost of the series.

The series is released weekly at midnight on Thursday night. It focuses on the week's events in the White House and for the president of the United States. In an effort to make the videos accessible to as many Americans as possible, they are posted on YouTube, the White House Web

site, and can be downloaded for free on iTunes. While the typical episode follows a fairly stable format of tracing the president's activities each day, there are special episodes that feature President Obama answering questions from citizens or focus on a particular issue of interest to the American public.

Anything shown in an episode of *West Wing Week* is watched by the Obama Press Office, and it has the right to refuse any material from airing. Critics have jumped on this as proof that the series is nothing more than official propaganda portrayed as genuine uncensored footage of the president at work. Others find the series interesting, but many critics believe that it is unnecessary since tax payers are paying for footage that the press corps is perfectly suited to cover. Further, the press corps does not have the ability to edit information in the same manner that the administration does. Some members of the press corps have complained about the access that *West Wing Week* receives. They are especially dissatisfied when events appear on the series that they were not permitted or invited to attend.

Looking at cost per view, the average episode of *West Wing Week* sees between 7,500 and 15,000 total views. While official costs have never been released for the series, given the low view count, one might question whether the production is necessary. Because much of the information presented in the series is already publicly available and known prior to the weekly release, some critics maintain that *West Wing Week* seems to be running more as a campaign tool than a governing tool. While there is unquestionably merit in showing the busy weekly schedule of the president through video instead of reported narrative, the cost-benefit analysis is yet to be completed. While *West Wing Week* is innovative and informative, viewership suggests that the American public is not responding to approximately 10-minute videos as much as they do a Facebook post or a tweet—at least not yet.

Whols

WhoIs is a search tool for gathering information about particular Internet domain names. Queries can be conducted using either a domain name search or using an Internet protocol (IP) address search. Results include the IP addresses and server information associated with a site, along with contact details for the person or company that registered the domain. In fact, the Internet Corporation for Assigned Names and Numbers (ICANN) requires that registrants provide accurate contact details for every domain they register, and that they update this information should it change. WhoIs databases date back to the earliest days of the Internet, and in its original 1980s incarnation, it allowed for free searches of information and easy data-mining.

As the number of domains and privacy concerns exponentially increased during the 1990s and after, queries were restricted in volume and required greater specificity or used CAPTCHA technology to limit abuse. In terms of social media and politics, WhoIs has played important roles in law enforcement and transparency, but has also created significant challenges for privacy advocates. As one of the earliest and longest-lived

aspects of the Internet, it encapsulates much of the tension between privacy and transparency that characterizes many other debates about the role of technology and information in a highly networked world.

Use

WhoIs has served a wide variety of functions for different users, including government and law enforcement. For authoritarian regimes, the ICANN registration requirements provide a potentially potent tool for tracking down political dissidents, assuming that people are accurately registering their details. A less well-known function associated with WhoIs relates to Regional Internet Registries (RIRs), which can use information from WhoIs to track IP addresses associated with not just those who own a domain, but also those who visit a given Web site. This same functionality is beneficial, even in more politically open societies, for law enforcement personnel. It has been especially useful in tracking down crimes associated with online fraud, spamming, hacking, online abuse, and child pornography.

Many law enforcement agencies would not only like to see WhoIs continued, but also strengthened to legally require accurate information that could be punishable if ignored or violated. Major holders of copyrights and trademarks in the arts, music, film, and other intellectual property industries also see a great deal of value in maintaining these capabilities and ensuring that the database is as accurate as possible. They can use it to track down people who pirate their property or who upload it to the Internet for pirating by others.

Privacy Concerns

While WhoIs is typically seen as beneficial in enforcing various criminal and property laws, it has been a major concern in the opposite direction for privacy law. The laws protecting the privacy of Internet users and domain name registrants vary between states, but WhoIs has been contentious for both Canada and the European Union, which have stronger privacy rights for the information contained in its database. There is a considerable body of opinion that contends that its existence is actually against the laws of these entities, and that it therefore requires substantial reformation.

A host of proposed reforms have been aired regarding WhoIs since the dotcom boom of the 1990s. Among the most popular and frequently mentioned reforms is allowing private registrants to hide their personal contact information from public display, much as people may choose to have a landline telephone number be unpublished in order to protect privacy. This reform has already been partially achieved through marketplace pressures and user demands because several domain name registration firms offer private registration services at an additional cost. These list the registrar, rather than the registrant, on the WhoIs database, thus protecting private address, phone, and e-mail data. However, when registrar services face difficulty or go out of business, this can make it difficult for users to prove their ownership of the domain and to have a record of their use of it. This is a rare, but not unknown occurrence, and so is a genuine concern for some users whose domain names are valuable business or personal assets.

A counter-reform movement has come from intellectual property activists and law enforcement, who want governments to enforce the requirements for accurate contact information in the database. These ends can be achieved without making the information public to the entire Internet, opening the possibility of preserving privacy in the general sense, while still allowing the information to be accessed by authorized personnel in the event of a suspected crime. Another significant concern from the “hidden WhoIs” service is that it makes it easier for profit-seeking individuals and companies to squat on domain names. Because a domain name can be an essential part of branding for a public individual or company, the prospecting for and purchasing of popular derivatives of common domain names, simply to charge high sums of money, is an expensive problem. Even more concerning for major firms is the inability to track down trademark violators for prosecution or civil lawsuits because it is much more difficult to trace information for registrants who use hidden WhoIs.

Scholars have suggested that WhoIs actually represents not just a tool for law enforcement and political control, but rather a real challenge to the state’s ability to govern. This is because its origin in the birth of the Internet created an

international norm of open access to information and transparency that has proven transformative to global political values. The continuation of WhoIs is a signal that these values are lasting and will continue to challenge state efforts to control information for the foreseeable future.

WikiLeaks

WikiLeaks (WL) is a nonprofit organization launched in 2006 that publishes information that governments and corporations have deemed secret or confidential. WL both conducts investigations and accepts information (or "leaks") from other sources, granting those sources anonymity. WL publishes its information—usually, original documents that it has found or been given, accompanied by its analyses of those documents—on its site, and also regularly provides its information to major media organizations around the world (including the *New York Times* in the United States, the *Guardian* in the United Kingdom, and *Der Spiegel* in Germany), typically under the condition that those outlets wait to release such shared material until or shortly after WL's moment of publication.

WikiLeaks classifies the materials it has published under 10 categories: war, killings, torture,

and detention; government, trade, and corporate transparency; suppression of free speech and free press; diplomacy, spying, and (counter-) intelligence; ecology, climate, nature, and sciences; corruption, finance, taxes, and trading; censorship technology and Internet filtering; cults and other religious organizations; and abuse, and violence, violations. Among the most discussed WL releases since the organization's founding are the *Collateral Murder* video (footage taken from inside a U.S. military helicopter showing the shooting of two Reuters journalists in Baghdad in 2007), the Iraq War Logs and Afghanistan War Logs (collections of hundreds of thousands of classified Pentagon documents about U.S. handling of those two wars), a cache of more than 250,000 diplomatic cables (e-mails, memos, and other internal communications between the U.S. State Department and its embassies worldwide), a set of over 700 secret files concerning the Guantanamo Bay prison, and the contents of Governor Sarah Palin's Yahoo! e-mail account.

In addition to information disseminated on its site, WikiLeaks has inspired a dedicated networked community of WL supporters and followers that regularly communicate on Twitter. Tweets published with the hashtag #WikiLeaks discuss issues of censorship and democracy broadly, promote WL and solicit donations, discuss specific WL leaks and the reactions to them, provide links (retweets) to news items, and provide calls to take political action around issues of concern to WL.

Operational Challenges

WikiLeaks was founded by Julian Assange, an Australian journalist and political activist, and a small group of like-minded journalists and computer experts, mostly unpaid and unwilling to reveal their identities. The group uses servers in Sweden, Germany, and the United States, among other locations, but has no official headquarters. While very active and frequently in the news in 2010 (the year that the *Collateral Murder* video, war logs, and diplomatic cables were released), WL has been relatively quiet since that time for a number of reasons. Chief among these was the arrest in Britain of Assange, who was accused by the government of Sweden of rape and sexual molestation involving two Swedish women. In summer 2012, Assange, hoping to

The WikiLeaks Mobile Information Collection Unit truck was stationed in lower Manhattan in New York City in November 2011 during the Occupy Wall Street protests.

avoid extradition to Sweden as well as possibly the United States, was granted political asylum by Ecuador, which allowed him to live in its embassy in London.

Further hampering WL's efforts are a financial embargo against the organization by VISA, MasterCard, Amazon, PayPal, and other companies that had previously allowed the organization to use their Web sites to solicit and accept donations, and the defection of several former WL employees. Among the most prominent defectors was Daniel Domscheit-Berg, a German journalist and computer expert who, after leaving WL, launched a whistle-blower site (OpenLeaks) and published a book exposing Assange's reportedly difficult personality and WL's questionable practices. Despite these setbacks, in summer 2012, WL released the "Syria Files," a set of more than 2 million e-mails between Syrian politicians, government officials, and corporations written over a six-year period, documents that WL believes will embarrass the Assad regime and its supporters.

Controversies

WL has been embroiled in controversy since its founding. The debates about WL begin with the organization's very definition. On its home page, WikiLeaks describes itself as a "media organization" and its members as "journalists."

Individuals and groups critical of WL's existence, methods, or effects have described WL as a "treasonous," or "cyber-terrorist" organization.

WL and its supporters argue that the organization provides transparency about government and corporate policies and practices, and as a result protects democracy, makes possible free speech, exposes government and corporate corruption, and allows citizens of countries around the world to know what their governments are doing. Journalists, media activists, and scholars claim that WL therefore serves the public interest and good, because the group exposes deception and counteracts government and corporate propaganda. At the same time, WL also has many detractors: a wide range of academics, social critics, and government authorities who have called WL's personnel (and their sources) traitors, threats to freedom and democracy, and perpetrators of terrorism.

They see WL as a threat to national security and international relations, as well as a danger to active-duty military, and have called for WikiLeaks to be silenced and its organizers prosecuted. Other ethicists, while not questioning the right of WikiLeaks to exist, have raised questions about the organization's tremendous political power, yet lack of political authority, about whether WL undertakes journalism or mere data dissemination, and about acceptable limits to the notion of free speech. What is beyond debate is the fact that WikiLeaks has changed the face of investigative journalism, brought into the open issues of government and corporate secrecy, and shed light on the impacts, both positive and negative, of the concealment and revelation of sensitive information.

WikiLeaks/Arab Spring

The Arab Spring refers to the revolutionary period of protests, demonstrations, and civil wars that spread across the Middle East and Northern Africa (MENA) beginning on December 18, 2010. For many, the Arab Spring connotes a democratic awakening in the Arab world. WikiLeaks is frequently credited as having a substantial role in the development of this civil unrest. On November 28, 2010, WikiLeaks released over 250,000 logs and cables providing insider information about many Western governments' secret dealings in financial and war matters in the MENA. "Cablegate," as the release became known, publicized the information and provided citizens tangible evidence to spark real political debate in the countries.

Using technology to incite political change is not a new phenomenon. For instance, U.S. President Woodrow Wilson's Fourteen Points speech in 1919 fostered uprisings in Tunisia, Egypt, and Libya after word of the address spread via telegraph. However, WikiLeaks offers a unique way of using information and communication technologies (ICT). Its functionality marks a period in history wherein media outlets can provide unrestricted access to an unedited dataset, which is available for download to anyone with computer access. Although it does not provide the public a space to discuss the documents, WikiLeaks offers citizens a tool to safely share potentially sensitive information with the world. At least in part, the WikiLeaks phenomenon offers the chance to fulfill the utopian vision of the Internet: Knowledge is power, and individuals can begin to influence major systems by overwhelming it with information.

Editor-in-chief Julian Assange helped launch WikiLeaks in 2007 with such a plan. The primary objective of the nonprofit media organization is to give world citizens access to news and information that would otherwise remain hidden. In order to encourage citizens to submit sensitive documents for public display, WikiLeaks provides an anonymous dropbox for users on its Web site. WikiLeaks gained notoriety after publishing its first major set of governmental documents, including detailed information about the Iraq and Afghanistan wars culled from confidential communications among 274 embassies around the world. Of the initial 251,287 cables released on November 28, 2010, 15,652 were classified as secret documents, 101,748 were listed as confidential, and 133,887 were categorized as unclassified. Private Bradley Manning (now Chelsea Manning) of the U.S. Army eventually pled guilty to providing WikiLeaks with most of these materials. Manning claimed that it discomfited him to know that certain information was withheld from the public, such as a video depicting U.S. helicopter pilots shooting down unarmed Iraqi civilians. He hoped that by releasing this information, the American public could engage in a vigorous debate on the military and foreign policy.

Mohamed Bouazizi and the Arab Spring

One of the more memorable dispatches released in Cablegate was from Robert F. Godec, the U.S.

ambassador to Tunisia. In the dispatch, Godec details his lavish stay at a Tunisian seaside resort owned by the son-in-law of President Zine El Abidine Ben Ali. Within the resort were many luxuries, including pet tigers and ice cream flown in from Saint-Tropez. Although many Tunisians knew about the extravagances of the president's family, many report becoming embarrassed that their secret was revealed to the world. Two weeks after the WikiLeaks release, 26-year-old street vendor Mohamed Bouazizi self-immolated in front of his governor's office after officials unfairly confiscated his wheelbarrow of produce. The dispirited university graduate likely knew about the leaked reports because Tunisia has one of the highest percentages of Facebook users, which probably compounded his frustration. Consequently, many associate Bouazizi's outrage over his treatment with the larger socioeconomic inequities in Tunisia that Cablegate publicized. On December 17, 2010, another two weeks after Bouazizi's self-immolation, the Tunisian Revolution began.

During the initial stages of the Tunisian Revolution, images of a hospitalized Bouazizi circulated the Web, inciting discussion among the citizenry. As news of the act spread, the government attempted to shut down citizens' Internet access. Hacker organizations such as Anonymous and Telecomix executed denial of service attacks to help protesters circumvent the blocks deployed by the Tunisian government. Moreover, news outlet Al Jazeera contributed to citizens' knowledge of the WikiLeaks reports, Bouazizi's death, and the revolution. The Tunisian movement inspired many other uprisings, which represented the largest protests in the MENA for over 30 years. For instance, protesters gathered in Cairo on January 25, 2011, Egypt's Police Day, to protest President Hosni Mubarek's regime, including its high unemployment, emergency law, and overall poverty. As the protests spread throughout the country, Mubarek cracked down on the uprisings.

However, much like Tunisia, Egypt has a very active online community full of dissidents and activists, who were organizing and mobilizing citizens against the purportedly oppressive regime. Such widespread and decentralized social support hindered the state's ability to shut off citizens' access to the Internet and information

about the protests. Moreover, many ISPs were slow or unresponsive to Mubarek's call to restrict service to citizens. At this point in the uprisings, both the revolutionaries and governments were discovering ways to control the political uprisings with social media. On the one hand, social networks helped dissenters by distributing PDFs to Egyptians detailing the injustices disclosed by WikiLeaks and describing how to assemble a successful protest. However, in spite of protesters' attempts to protect their communications with Tor and Anonymous, the Egyptian government was able to use social media to track who was speaking out. Social networks also allowed the government to infiltrate the networks to spread misinformation. Although protesters could use Google Maps and other social media to verify sources, social networks became less safe for open dialogue.

Colonel Muammar Qadhafi warned the people of the MENA in mid-January that they should not be tricked by WikiLeaks or listen to lying ambassadors. However, despite this warning, Libyan citizens began a series of peaceful protests on February 15, 2011. Qadhafi tried to quickly disperse the crowd, as well as shut down the country's Internet access. However, major media outlets had already picked up the story, such as the *Guardian's* reprinting of the WikiLeaks cables, which were seen by many in Libya. Consequently, the revolts continued to spread across the country. The civil unrest further spread into Jordan, Bahrain, Palestine, Saudi Arabia, Syria, and Yemen. Similar to Tunisia, Egypt, and Libya, most of these dissenters began their organization online. Social media outlets and traditional media sources worked in harmony to stoke the flames of dissent by continuing to publish articles from WikiLeaks' site and spread information about the protests. Although the unrest in Tunisia, Egypt, and Libya led to the successful ousting of their corrupt presidents, countries like Jordan and Saudi Arabia merely wanted their leaders to address a broken economic system. As of late 2013, Syrians are still engaging in a civil war to determine the outcome of their revolt.

Social Media as Revolutionary Tool

As witnessed in the Arab Spring, the structure of ICTs have changed the way that social movements

operate, especially in regard to organization, communication methods, and the speed of their transmission. Many researchers currently describe the potential use of social media as both a space and a tool to organize and discuss issues. Social media as a space allows for discussion, focusing on the communal and decentralized sharing of information. In order to create such Internet spaces, users employ tools such as Twitter and Facebook to share information. Thus, one major change of ICTs is the way they provide tools to facilitate the horizontal spread of information among users.

During the Arab Spring, social media also functioned as a method of organization. Although many protesters during the Arab Spring claimed that “the social network is us,” Facebook and Twitter offered citizens a space to discuss meeting times, generate plans for action, and compose a cohesive message, without the help of the mainstream media, by using resources such as WikiLeaks. Online collaboration revealed that there was a critical mass for collective action not seen in previous attempts at revolt in the MENA. For instance, although uprisings arose in Egypt in 2007, many major media outlets did not cover the events. However, with the help of WikiLeaks, Facebook and Twitter made it easier to recruit members and share information focused on a central issue.

This neatly packaged uprising provided major media outlets with a clear group message and substantial research to support claims, emphasizing the importance of the social unrest and making the news easier to publish. Also, the mass of public unrest publicized among a host of social network users forced elites in the region to stop propping each other up. It forced places like the United States to support the side of democratic choice, not the political class, who ruled with power and an iron fist. Once the countries’ issues went public, protesters had the tools to provide enough penetration to quickly send the information to less politically active citizens.

Social media also hindered some citizens’ efforts during the revolutions of the Arab Spring. Although social media allowed citizens to bypass traditional gatekeepers, many found themselves confronted with new gatekeepers, usually Internet censors with more dangerous potential. Governments and businesses dealt with new types of

information sharing on the Internet as dangerous because it compromised both types of organizations’ secrets.

WikiLeaks and the Arab Spring taught the world several things about social media and political movements. First, knowledge is power. Although WikiLeaks did not provide citizens with much new information, once the world was forced to publically recognize these acts and the regimes in the MENA tried to block access to the information, citizens had more leverage to revolt. Second, as social media use increases, citizens are able to collaborate with traditional media to fan the flames of a successful revolution, which gives citizen activists and journalists more power in world affairs. Third, WikiLeaks demonstrates that social media and new media outlets have the power to lift the metaphorical veil that covers the public’s eyes from understanding the intricacy of events around the world. Although WikiLeaks faces various legal, ethical, and moral issues, the organization’s biggest opponents are major governments, military outfits, and corporations, which shows the power that such a Web site can have in political affairs.

Wikipedia Misuse

At Wikipedia, a free, nonprofit, online encyclopedia staffed primarily by volunteers, anyone can be an article contributor. There is no screening process in selecting who becomes an (often anonymous) contributor, and only rarely is a peer review process held before the entry is made public. While technically, anyone can publish an article about anything in Wikipedia, it has a rather intricate set of rules about what can be written about, with articles not meeting the criteria of being encyclopedic facing deletion within days of being posted. Articles are also subject to various forms of peer review over time, particularly if they are to be featured on Wikipedia's front page.

Wikipedia uses the "bazaar model" of knowledge production, or what has been described as "commons-based peer production" and "good faith collaboration." Ideally, in a community where creating good, reliable content is the easy and rewarded norm, malicious contributions are eventually going to be spotted and stomped out. According to Wikipedia, one of the most effective techniques for policing the site's content vulnerability is something called WikiScanner. Invented in 2007 by Virgil Griffith of the California Institute of Technology, this is an online tool that traces the edit history of Wikipedia articles and links them with IP addresses. It is effective with all "volunteer editors" except registered Wikipedia editors, who remain anonymous to all but the inner circle of the Wikipedia administration. As a means of ferreting out inappropriate changes made to Wikipedia entries by corporate and political vested interests, WikiScanner has detected hundreds—if not thousands—of blatantly self-serving edits made by political spin doctors and strategists, politicians, government organizations, corporate marketing/PR professionals, and ideologically overzealous members of the Wiki community.

Wikipedia's "anyone can edit" model allows for much more misuse than traditional encyclopedias. Of serious concern are hoaxes and deliberate pushing of a certain point of view—on Wikipedia colloquially known as "POV-pushing." Since the beginning, Wikipedia has struggled to make itself more robust to such abuse, yet it can never fully

eliminate it without going against its very nature as a site that "anyone can edit." Thus, while a randomly sampled Wikipedia article should be reasonably well written and neutral, it is also a good bet that in the millions of its articles, at any given time, Wikipedia sports a hoax, an advert, a vanity autobiography, political propaganda, and other "exceptions to the rule" that have slipped through the cracks of its volunteer-run quality control. Most such pieces are deleted or fixed within a matter of weeks, if not days, and a casual reader is unlikely to ever run into one—but they always lurk. Of course, the fact that many if not most errors or deliberate distortions in Wikipedia material are corrected eventually does not protect against the dissemination of inaccurate material during the period between when it is posted and when it is fixed.

The most famous example of misuse of Wikipedia remains the Seigenthaler controversy. In 2005, some defamatory claims were introduced into a biography of noted American journalist John Seigenthaler. After a few months, the errors came to public attention and were removed; however, Seigenthaler vocally criticized Wikipedia for allowing such false information to be publicly displayed for several months. Wikipedia's response to this is enlightening: in the months following the incident, a new set of policies was introduced, with much more stringent screening for biographies of living persons.

Since then, Wikipedia has been subject to a number of other incidents. U.S. congressional aides tried to remove undesirable information from biographies of certain congressmen. Companies and individuals have offered money to editors to create or edit various entries. Controversies have erupted over Wikipedia's hosting of Muhammad cartoons or pornographic images. Wikipedia volunteers had to create a "court" to preside over cases of biased editing in a number of topics, from Scientology to fusion power. A number of debates have been going on for years, with editors constantly debating issues such as the naming of articles (e.g., "pro-life" or "anti-abortion").

Conclusion

Wikipedia represents a new type of information resource, one where the line between providers and consumers of information is blurry. While it is

open to forms of misuse to which more traditional media are immune, it is also much more transparent, and potentially democratic than old media.

Wikis and Collaborative Project Web Sites

Wikis and collaborative project Web sites are Web-based, hypertext-authoring systems that allow for collaborative production, modification, and maintenance of content. They allow users, most often anonymous or pseudonymous, to add, edit, delete, or hyperlink content directly from a Web browser, without learning HTML. Wikis (*wiki* is the Hawaiian term for "quick") and collaborative project Web sites provided an easy-to-use alternative to text-only and unidirectionally hierarchical Web sites accessible only to the most technologically literate. Wikis are used for a variety of purposes, including textbook production, software documentation, and political and other specialized community-based

discourse. They are often part of a larger Web site, allowing organizations or political campaigns to engage geographically dispersed customers and constituents.

The interfaces of wikis and collaborative project Web sites widely differ. Because they are driven by collaboration and participation, wikis often feature a minimalist design with linked pages. While some limit access to these pages, others allow direct content production with little to no editorial oversight or password protection. A high-profile wiki is the online encyclopedia Wikipedia. Wikipedia is a free, open-access, Web-based encyclopedia with editions in nearly 300 languages. Its 23 million articles are written by over four million active contributors and read by over 360 million people worldwide.

Users can edit content simply by clicking on the "Edit This Page" button displayed on the interface. The edits are then reviewed by the site's administrators to ensure accuracy and appropriateness. The success of Wikipedia—it competes with *Encyclopedia Britannica* for visitors—is largely because of its low cost and user friendliness, combined with a minimally hierarchical structure that ensures accuracy. Recently, with its user-generated coverage of news events such as the 2012 U.S. presidential election and the Virginia Tech massacre, Wikipedia has also become a news source that competes with traditional outlets.

Wikis and collaborative project Web sites provide new and varying nonhierarchical venues for interaction with and among voters. By engaging voters at the grassroots level with a direct and reciprocal link to policymakers, wikis appeal to digital natives comfortable and competent with new media technologies. The low production costs of wikis and collaborative project Web sites can also provide a sense of agency and engagement for the disenfranchised. Wikis and collaborative project Web sites have been employed by cities, organizations, and political parties and campaigns to spread information and encourage political participation, with mixed results. The Green Party of Canada's Living Platform and its successor, OpenPolitics, feature brief, short-lived, and interconnected descriptions of issues and candidates. The City of Pittsburgh's Platform Pittsburgh and Utah politician Pete Ashdown's 2006 and 2012 campaigns for U.S. Senate allow voters to discuss

issues and organize rallies. Finally, NOLA-Intel was set up by the City of New Orleans to spread information to citizens after Hurricane Katrina.

WikiScanner and Political Spin Doctoring

Released to the public via the Internet on August 2007, WikiScanner was a program that allowed users to trace the possible editors of Wikipedia articles by determining the location and owner of the computer that had generated the edit. Wiki Scanner caused considerable controversy by allegedly exposing a range of instances of spin doctoring on Wikipedia, where articles had been modified by both corporate public relations and government staff to create a positive or negative spin or attitude on particular brands, persons, and organizations. Academics, politicians, and media activists have argued that WikiScanner is one of a range of technologies that have highlighted possible problems with a lack of credibility in collaborative, user-led information sites like Wikipedia.

Wikipedia operates on the principle of a global digital democracy in the generation of knowledge, in which, as the site states, "each new editor can

offer new insights on how to enhance the content" of Wikipedia at "anytime." Contributors to the online information database, referred to as Wikipedians, can either login to the site with an established username, or can anonymously offer material and edits. It has been argued that it is the capacity for anonymous edits on Wikipedia that generates the possibility of spin doctoring on the Web site by users with vested interest in the content of Wikipedia pages. Wikipedia has clear policy guidelines on the need to maintain a "neutral point of view" in online submissions to its database, and strongly discourages conflict of interest (COI) edits on its site, meaning that users with a personal, political, or corporate stake in specific Wikipedia content should not be involved in the creation or editing of that content. However, because there is no single editorial body overseeing Wikipedia, the site maintains no guarantee of the validity or truth of its material. In the early 2000s, these issues with credibility were exposed in a series of reports that U.S. congressmen were editing their Wikipedia pages in order to enhance their public profiles, and that Wikipedia's cofounder, Jimmy Wales, admitted that he had edited the content of his Wikipedia page.

It was out of this context of concern over the possibility of doctoring content on a purportedly neutral Web site that U.S. graduate student Virgil Griffith created WikiScanner. A major in computation and neural systems, Virgil decided to use his skills to build a program that would remove the possibility of anonymity in the Wikipedia editing process, and thus potentially expose instances of deliberate spinning of Wikipedia material. He created WikiScanner by listing all anonymous edits from Wikipedia (sourced from a publicly available database) and tracking the Internet protocol (IP) addresses of the edits using a program called IP2Location. While this tracking process could not determine the identity of the person who had created the edit, it could identify the geographic location and company or department name of the source, and thus reasonably conclude that the edit came from someone with access to the source's network.

WikiScanner evolved into a database of 34.4 million edits, carried out by 2.6 million individuals or organizations across the political, social, and corporate spectrum. The program demonstrated

that while many forms of editing occurring on Wikipedia were legitimate, three key types of anonymous editing were directly related to political spin doctoring: the removal of paragraphs of information containing negative content, white washing or replacing negative adjectives with positive ones, and adding negative information to a competitor's page.

Soon after its release, WikiScanner became the topic of a number of news media articles and blog posts on the issue of political spin doctoring on Wikipedia. In 2007, the *New York Times* reported that WikiScanner had shown that U.S. firm Diebold Election Systems had removed 15 paragraphs on industry concerns over the integrity of its voting machines and on the close relationship between the company CEO and President George Bush. The same year, Australian media outlets alleged that WikiScanner had detected more than 5,000 edits made by employees of the Australian Defense Department, and a total of 126 edits by the Australian Department of Prime Minister and Cabinet on material potentially damaging to the reputation of the Australian government. It was also purported that a Vatican computer had removed Wikipedia references linking Ireland's Sinn Fein leader Gerry Adams to a historical murder, and that CIA employees had changed entries on the U.S.-led invasion of Iraq in 2003, and that the agency had enhanced the Wikipedia portrayal of Pope Benedict XVI.

Instances of spin doctoring were reportedly not limited to the political domain. Users of WikiScanner used blogs and social media sites to allege that a number of corporations had been actively engaged in editing Wikipedia content. It was charged that Pepsi, for example, had removed content on the long-term health effects of its product, that ExxonMobil had removed content on the scope of the environment impact of its 1989 *Exxon Valdez* Alaskan oil spill, and that the Dow Chemical Company had deleted part of an entry on Union Carbide and the Indian Bhopal disaster of 1984. It was also alleged that U.S. retail firm Walmart changed an entry on the wages of its workers, removing a claim that its wages were significantly less than those of other retail stores, and replacing it with one that read that Walmart employees earned almost double the minimum wage.

WikiScanner appears no longer to be in operation; however, it played an important role in bringing the issue of spin doctoring on Wikipedia to public attention, and rose the issue of reliability and credibility on "neutral" user-led Web sites in the collaborative environment of Web 2.0. A number of sites that operate on the same principles as WikiScanner have been developed in the early 21st century, including WikiTrust, released in by the Online Collaboration Lab of the University of California, Berkeley, in 2009; and WikiWatchdog, released by Italian researchers Frederico Scrinzi and Paolo Massa in 2012.

World Can't Wait

The U.S.-based organization the World Can't Wait was founded in January 2005, following the 2004 election. The World Can't Wait campaign challenged the idea that the only way to combat what they viewed as the ongoing ills of the George W. Bush/Dick Cheney administration was to recruit a new form of voice for the American electorate.

This notion was that a counterforce could originate as a mass movement of people who were educated on the crimes and manipulation of the U.S. government, rather than a more traditional

movement with roots in the Democratic Party. Since its inception, the World Can't Wait has held numerous demonstrations, beginning with the Call to Drive Out the Bush Regime, and moving on to more recent projects, focusing on putting an end to Guantanamo Bay prison.

The first demonstration, nicknamed The Call, was a written statement of a list of grievances created by the organization's followers. Some of the grievances included in the document were the suppression of science in favor of religion, and the American lifestyle of bigotry and nationalism. World Can't Wait began by handing out millions of copies of the list of grievances, which supplied thousands of supporters for the brigade. Later, the *New York Times* and *USA Today* published the full statement, which eventually included 40,000 signatures of approval. Some of the signatures

included former California Senator Carol Midden, actress and activist Jane Fonda, and author Gore Vidal.

One project that the World Can't Wait campaign has worked on is an attempt to close the U.S. detention camp Guantanamo Bay. In the last few demonstrations regarding the prison, volunteers rallied together wearing orange jumpsuits and t-shirts to represent the orange jumpsuits of prisoners. May 17, 2013, marked the 83rd day of a prisoners' hunger strike. Of the 166 prisoners detained at Guantanamo Bay, only nine of them have been charged with a crime relating to terrorist activities within the United States. The others have been held for the last 11 years without a trial. The hunger strike is the prisoners' way of defending their rights while hoping to draw attention to their plight.

World Can't Wait volunteers demonstrating for the closure of the Guantanamo Bay prison during the George W. Bush administration. They wore orange jumpsuits and black hoods during this protest in Upper Senate Park in Washington, D.C., on January 4, 2007. The organization also makes use of social media, video conferences, audio tapes, and public service announcements.

The primary concern of the World Can't Wait foundation is that traditional media are not accurately portraying the crimes of the government. Currently, they claim that news and media outlets focus on terrorist attacks in the Middle East, the economic crisis in Europe, or shootings and robberies here in the United States. However, the information that is not shared via news Web sites and conferences is the direct role of government in the social and political troubles of the world. Media outlets, they claim, do not spread objective knowledge, but rather entertainment. The World Can't Wait campaign attempts to combat this through the use of social media, issuing press releases, video conferences, audio tapes, and even public service announcements. The drive to keep America informed about governmental action, whether constructive or deleterious, is the sole motivation of this foundation.

under the continued directorship of Jeffrey Cole), the WIP believes that "the effects of the Internet may surpass those of television and could someday rival those of the printing press." Because it deems the Internet "the most important technological development of our generation," the WIP chose to document the Internet's "evolution," rather than provide backward-looking "post-scripts." It provides up-to-date global snapshots of Internet usage and attitudes, rather than conducting after-the-fact historical analyses in labor-intensive work. Thus, the WIP expanded from a collaboration of three universities (UCLA in the United States, NTU School of Communications in Singapore, and Bocconi University in Milan) to one that includes 37 countries. Such expansion enables robust international comparative study of the Internet.

Partnering with universities and research centers worldwide, the WIP has produced four research reports. Drawing on face-to-face interviews and telephone surveys, the most recent report, the fourth edition of the International Report for the World Internet Project, was published in 2012. The report includes 11 national status reports that describe the history of the Internet in corresponding countries, as well as its cultural significance and regulatory framework.

The 11 nations represented in the report are: Australia, Canada, Colombia, Italy, Mexico, New Zealand, Poland, Spain, Sweden, Switzerland, and the United Kingdom. National status reports identify key trends, including the finding that 45 percent or more of Internet users go online to find health information on a monthly basis, with the exception of Colombia, where only 19 percent of users have searched the Internet for health information.

The 2012 report also provides comparative data on topics such as freedom of expression, news content, social networks, and online purchasing. Previous international reports published by the WIP contained data on similar topics. Additionally, such reports have found an inverse relationship between Internet use and age (the younger the user, the more time he or she spends using the Internet on a daily basis). Findings also point to a trend related to Internet adoption across income levels: Individuals in the bottom half of household income scales are less likely to adopt

World Internet Project

The World Internet Project (WIP) was created in 1999, with the intent to collect data about the uses of the Internet and views of users and nonusers across the globe. Founded by the Center for Communication Policy at UCLA (now the USC Annenberg School Center for the Digital Future

the Internet because it seems like an unnecessary expense for those who earn less. New findings have also emerged in the data. The latest report shows that in all countries except Poland, male users outnumber female users. Mexico and Italy report the largest gender gaps in Internet usage.

Addressing issues such as education, politics, consumption, interpersonal communication, freedom of expression, and privacy, the WIP generates data that may inform political, regulatory, educational, and corporate agendas. For example, the 2012 report found that in all of the project's participating countries except Poland, the Internet is used by at least 75 percent of students (age not identified) for school-related work on a weekly basis. This study informs discussions on accessibility of a technology and its potential for educational use. The 2012 report also investigated the Internet's perceived effects by users and nonusers on the political process. Users, unlike nonusers, viewed the Internet as a means to inform citizens about the political process.

In addition to compiling information on Internet users and nonusers around the world, the WIP expands upon such research by discussing broader relationships between Internet use and consumption of other media. For example, the 2012 report found that Internet users tend to rely on television and the Internet more than on radio and newspapers for entertainment. More Internet users in Australia, New Zealand, Poland, Sweden, and Switzerland value television as a source of entertainment, compared to users in Canada, Colombia, Mexico, and Spain, who prefer the Internet as a source of entertainment above other media. Thus, the WIP informs international comparative analyses of how Internet users consume and value other media.

By researching "reasons for not going online," the WIP also informs debates about barriers to Internet consumption. For example, the top reason that nonusers gave for not using the Internet was that they had "no interest" in going online and perceived the Internet as "not useful." The second and third most popular reasons for non-use were participants' lack of understanding about how to access and use the Internet, followed by prohibitive cost.

One unique aspect of World Internet Project is its reach beyond academia. The WIP makes its

findings available to communities, organizations, groups, and governments around the globe. For example, the project offers government officials access to its data online to share information that may boost citizens' understanding of voting processes.

Conclusion

The World Internet Project is a valuable research tool that provides overviews of Internet usage and perceived values with impressive breadth and depth. The latest report has something for every scholar, policymaker, educational leader, and Internet marketer to consider: It explores topics including consumer opinions, personal finances, politics, health care, gender equality, and education.

Former U.S. Secretary of State Hillary Clinton envisioned a future of Internet freedom worldwide when she described the ability to connect to the Internet as a key component of freedom of expression, association, and assembly. In 2012, the United Nations concurred by stating that the Internet is a human right because of the medium's ability to promote innovation, expression, and free-flowing ideas around the world. The founders of the WIP foresaw the importance of the Internet back in 1999, and has been documenting its impact ever since.

World Press Freedom Index

The World Press Freedom Index is an annual ranking of countries by level of press freedom. It measures the degree of liberty that journalists enjoy and the efforts made by authorities to respect and ensure respect for this freedom. The index is compiled and published by the French nonprofit, nongovernmental organization Reporters Without Borders. To rank a country's press freedom, Reporters Without Borders uses a questionnaire that is filled out by partner organizations, 150 correspondents, journalists, researchers, jurists, and human right activists. Data are collected yearly, and the index measures the level of freedom that journalists, news organizations, and Internet users have in their countries by looking at six main variables: pluralism, media independence, environment and self-censorship, transparency, legislative framework, and infrastructure. Each variable comprises a set of "yes" or "no" questions, and/or questions with numerical scaling ratings. The answer can range from a score of zero (meaning no self-censorship) to five (strong self-censorship). Each variable receives a score from 0 to 100, with 0 being the best score and 100 the worst. The overall score is calculated on the basis of these six scores.

Pluralism measures the degree of representation of different opinions in news reporting. The more the news media report about different ideas, beliefs, and stances, the more a country is considered pluralistic and democratic. For many analysts, media pluralism is directly related to media concentration, that is, the status of news media ownership. High media concentration means that fewer individuals or organizations control news organizations and their news agenda, whereas low media concentration indicates the presence of diverse media owners in a country. It is believed that low media concentration points to more pluralistic media in a country because the presence of various media owners may guarantee a certain level of diversity of news. Globally, the top five large private media owners are the Walt Disney Company, News Corporation, Time Warner, Viacom, and CBS Corporation. These media conglomerates

control the majority of news production across the world.

Media independence measures the extent to which media organizations are independent from political and economic powers. Political parallelism, that is, the political orientation of news media and the role of state intervention in media management, are two important dimensions that affect media independence. High political parallelism indicates a tight relation between those in power and news media, which could lead to some control on the type and form of content presented in the news. A low role of the state in, for instance, subsidizing media organizations, would suggest less freedom in media coverage because news organizations will be financially dependent on businesses and will focus on covering only issues that are economically convenient, instead of covering diverse opinions. Yet, state subsidiaries, when accompanied by specific political requests, may have the opposite effect.

Environment and self-censorship measure the settings in which journalists work. Respondents are asked to express their opinion on the news organization they work for, on whether they feel abuses of powers, receive bribes, or are told to censor activities. This variable is the most difficult to measure because of the subjectivity of responses. Different understandings of ethics and different standards make the measurement of this variable hard to compare across countries. Transparency measures the openness of the news organization and the procedures that affect the production of news and information, specifically in relation to how journalists obtain information and the extent to which they disclose the source of information and interests behind different news. This variable is tied to the environment and the presence of censorship, thus it bears similar reliability problems. To benchmark transparency, Reporters Without Borders looks at the level of professionalization of journalists, the existence of codes of ethics, and the procedures for obtaining a professional journalist's license and for receiving foreign journalists' accreditations.

Legislative framework analyzes media policy and legislation in each country, including the level of policy effectiveness and enforcement. There is no uniformity in legislation. In some countries, freedom of expression and press freedom are

guaranteed in constitutional specifications. These sometimes include governing laws on media operations; other times, media laws are confined to broadcast media. In these cases, broadcasting regulators are responsible for issuing licenses and enforcing compliance with license conditions, including ethical standards. More recently, across the world, a number of countries are starting to converge and integrate their media and communication policies. Convergent legislative frameworks typically include information on the objectives, regulatory principles, and role of regulators, the treatment of content regulation, the use of general competition law, and approaches to the Internet and online environment.

Infrastructure measures the quality of the infrastructure that supports the production of news and information. It is a variable assessing the structural conditions of media freedom because it also appraises the structure of the media market, such as newspaper circulations rates and readership. Media infrastructure often goes hand-in-hand with legislative framework and media pluralism variables because a country's media infrastructure is highly affected by legislation and the presence or limited presence of diverse media conglomerates.

While the index is not meant to assess the democratic status of a country, the World Press Freedom Index is tied to the political system of each country. In other words, the results often show that press freedom is challenged in political systems where authoritarian or controlling forms of governance exist. This means that democratic countries typically occupy the top of the index, whereas dictatorial countries occupy the last positions. The index has been criticized for offering biased evaluations of countries' press freedom because the questionnaire is formulated according to a view of media freedom that is inclined toward an understanding of the concept of "freedom" reflecting a specific region of the world, that of Western countries, according to John Burgess. Yet, the World Press Freedom Index is used to raise awareness on the working conditions of journalists across the world and to provide valuable information to regulators and policymakers.

World Wide Web, History of the

The basic principles behind the World Wide Web (WWW) were developed in 1989 by Tim Berners-Lee while he was working at CERN, a physics research laboratory in Geneva, Switzerland. The following year, Berners-Lee and his colleague Robert Cailliau presented a refined version of the concept in a paper that laid out the Web's basic components. The WWW is a software application that runs on the Internet, while the Internet is a network of hardware such as computers, servers, routers, switches, wires, cables, wireless transmitters, satellite connections, and the associated protocols for transmitting data across that network. However, once the WWW became the dominant platform for using the Internet, the two merged in their development and in the minds of most people.

The Internet is a network of networks that began as the ARPANET developed by the Advanced Research Projects Agency (ARPA), a unit of the

U.S. Department of Defense. The ARPANET was designed to test the feasibility of distributed networking, combined with packet switching technology. A distributed network, as opposed to a centralized network, is not controlled in one central location, but contains many nodes and routes through which information can travel. Thus, if one node is inoperable, or one route is blocked, the information packet chooses a different route. Packet switching divides the message into numerous packets; each packet selects the most expeditious route through the network, and then it is reassembled at the destination, thus more efficiently and robustly utilizing the network than circuit switching.

Defense contractor Bolt, Beranek and Newman (BBN) received the contract to build the network, and in 1969 the ARPANET went online, connecting a computer at UCLA with a computer at the Stanford Research Institute. By April 1971, a total of 15 computers were on the network. Initially, the ARPANET was mostly used for file transfers and remote time sharing of computers, but in 1971, Ray Tomlinson, an engineer at BBN, developed e-mail, and by 1972, over half of the network's traffic was e-mail. Throughout the 1970s and 1980s, more computer networks, mostly within the academic and scientific research communities, connected to the Internet, and by October 1992, over 1 million computers were online. However, Internet use was still mainly confined to government, academic, and scientific communities, and it was mostly used for e-mail, file sharing, chat rooms, forums, and games. More than 20 years after its beginning, the Internet was used by less than 1 percent of the world's population. The WWW popularized the Internet and turned it into a mass medium for communication and commerce.

Development of the World Wide Web

Berners-Lee wrote his WWW software to provide a standardized method for members of the scientific community to share research and hyperlink to one another's documents. His original design for the WWW consisted of three main elements: universal resource identifiers (URIs, later changed to URL for universal resource locator), hypertext transfer protocol (HTTP), and hypertext markup language (HTML). The URI provided a unique address for every item on the Internet, HTML was

the language for using and displaying Web pages, and HTTP provided the protocols that computers would use to communicate over the Internet when using the WWW. By the end of 1990, Berners-Lee had also developed the first Web browser, the program for accessing and presenting pages in HTML, as well as the first Web server, the software that stores Web pages on a computer, allowing others to access them. This system, allowing users to link or hypertext from any point on the network to any other, is the basis of the WWW as it exists today.

Berners-Lee had written his WWW software on a NeXT computer, and in March 1991, he released the program to a limited number of NeXT users at CERN. In August, he put it onto the Internet, although it had limited functionality for anyone not using a NeXT computer. Interest in the WWW gradually spread among academic and scientific communities, and in 1992, Web browsers were developed for the Unix and Macintosh operating systems. In April 1993, CERN officially announced that the WWW software could be freely used by anyone.

Early Web browsers all had shortcomings that made them difficult for the average person to use. Mosaic, released in 1993, was the first user-friendly and widely popular Web browser. Developed by a team led by Marc Andreessen at the National Center for Supercomputer Applications at the University of Illinois at Urbana-Champaign, Mosaic was downloaded by more than two million people within a year of its release. Mosaic made the Internet easier to navigate and created a more graphically pleasing interface for users. By 1995, the WWW had replaced file transfer protocol (FTP) as the main software application, other than e-mail, used on the Internet. E-mail providers adapted by making their software compatible with the WWW, and by 1996, Web-based e-mail services such as Hotmail began to appear.

Dot-Com Boom

The dot-com boom (also sometimes called “the Internet boom” or “bubble”) lasted from roughly 1995 to 2001, when the technology-heavy NASDAQ stock index rose 500 percent, and the widespread commercialization and popularization of the Internet took place. In 1995, the U.S. government transferred control of the Internet to the private sector, and the Telecommunications Act of 1996 created a favorable regulatory environment for the expansion of the Internet. The dot-com boom was kicked off by the Netscape initial public offering (IPO) in August 1995, when the company’s stock price rose by over 100 percent on its first day of trading, and was 600 percent above its IPO price by December. The Netscape Navigator, a commercial version of the Mosaic browser, was developed by Andreessen and other members of the original team that had created Mosaic. Released near the end of 1994, Netscape Navigator had been distributed to over five million users by May 1995, giving it a 60 percent share of the browser market. In August, Microsoft also entered the browser market by releasing its Internet Explorer.

The dot-com boom ended in 2000, with the NASDAQ stock index peaking at over 5,000, then losing 78 percent of its value by 2002. However, the boom of 1995 to 2000 provided investment from the financial community that expanded the Internet and transformed the personal computer from a stand-alone computational and word

processing device into a networked, mass-communication device for the delivery of media content. In 1995, there were fewer than 20,000 Web sites on the WWW, and only 16 million Internet users worldwide; but by the end of 2000, there were over 25 million Web sites and the number of Internet users worldwide had risen to 361 million.

Politics on the Web

The Internet was first used in presidential campaigning in the 1996 election as candidates created Web sites and used e-mail to communicate with their supporters. Bob Dole made history by being the first candidate to give out his Web site address during a presidential debate. The Web had little impact on the 1996 presidential election, but a few years later, it became apparent that the Web could radically alter politics by making it easier for nonestablishment candidates to bypass traditional media and the major political parties. In 1998, Jesse Ventura, a former Navy SEAL and wrestler running as a third-party candidate, shocked the political world by using e-mail and his Web site to generate grassroots support, raise money, and win election as governor of Minnesota.

In the 2000 presidential primaries, Bill Bradley used the Internet to raise over \$1 million in his unsuccessful effort to take the Democratic presidential nomination away from vice president Al Gore. Also in 2000, John McCain made an unexpectedly strong bid for the Republican presidential nomination, driving traffic to his Web site to generate over \$6 million in online contributions before finally losing to the more established candidate, George W. Bush. During the 2000 presidential election, Bush and Gore created Web sites, accepted online contributions, and communicated with supporters via e-mail, but still largely ran their campaigns in the traditional manner.

For the 2004 presidential primaries, Howard Dean used the Web to a greater extent and more effectively than any previous presidential candidate. Dean used blogging and social software tools to involve supporters in the campaign and create a loyal grassroots network and fundraising base, attracting over \$20 million online before withdrawing from the race for the Democratic nomination. In the 2004 general election, John

Kerry followed a Web strategy similar to Dean's to bring in nearly \$82 million in online contributions. The Bush campaign mainly used its Web site to organize and communicate with supporters, ultimately raising \$14 million online. Both presidential campaigns created blogs, and both the Democratic and Republican parties invited bloggers to cover their conventions that year.

In his quest to win the 2008 presidential election, Barack Obama was able to draw upon the infrastructure for online campaigning that had been created by the Dean campaign. Obama broke all previous fundraising records by receiving over \$500 million in online contributions from three million donors. The Obama campaign assembled an e-mail list of 13 million supporters, networked its Web site with popular online addresses, and used social media to develop numerous online communities. In 2012, the presidential campaigns of both Obama and Mitt Romney made use of social media platforms such as Twitter, YouTube, and Facebook, as well as smartphone applications.

Web 2.0 and Social Media

By the early 2000s, the term *Web 2.0* was popularized to describe Web applications that allow users to create content and interact with one another. Social media sites (also called social networking sites) are a primary example of Web 2.0 technology because they allow users to interact, collaborate, build networks, microblog, and post comments, links, pictures, or videos. Precursors to social media sites existed in the form of chat rooms and Internet forums beginning in the 1970s, as well as dating and match-making sites that began appearing as far back as the early 1990s. However, Boyd and Ellison consider the first true social networking site to be SixDegrees.com, launched in 1997. SixDegrees attracted over a million users, but it failed to develop a sustainable business model, and it closed in 2000.

Numerous social media sites were established in the late 1990s and the early 2000s, but Friendster, started in 2002, quickly attracted millions of users and became the most popular social networking site before being overtaken in 2005 by Myspace (launched in 2003). In 2008, Facebook replaced Myspace as the world's most

popular social media site, and in 2009, use of social media surpassed e-mail as the single most popular activity on the Internet. By 2012, there were hundreds of social media sites on the Web, many designed to appeal to users interested in specific topics such as arts, cooking, fashion, music, photography, politics, news, and religion, but the two most popular social networking sites were Facebook and Twitter. Founded in 2004 by Mark Zuckerberg, Facebook surpassed 100 million users in 2008, exceeded 500 million users in 2010, and by 2012 had over 900 million registered users worldwide and an estimated 750 million unique visitors a month, over half of whom accessed the site via a mobile device. Twitter, a social networking and microblogging site founded in 2006, had an estimated 250 million users by 2012, 60 percent of whom accessed the site via a mobile device.

With the release of Apple's iPhone in 2007, Google's Android operating system in 2008, and Apple's iPad in 2010, more people began accessing the Internet via mobile devices such as smartphones and tablets. In 2010, for the first time, worldwide sales of mobile devices exceeded worldwide sales of personal computers (including laptops and netbooks), and two years later, almost five times as many mobile devices as personal computers were sold worldwide. By 2012, about one-third of the world's population was online, and there were at least 6.89 billion indexed Web sites.

World Without Oil

World Without Oil is an alternative reality game (ARG)—and a serious experiment—that took place on the Internet from April 30, 2007, to June 1, 2007. In *World Without Oil*, players from all over the world simulated the first 32 weeks of a global oil crisis. Its slogan was "play it before you live it." An Independent Television Service (ITVS) Electric Shadows project and Independent Lens Production funded by the U.S. Corporation for Public Broadcasting, the Web presentation was designed and produced by the Writerguy Team, consisting of independent game writer and designer Ken Eklund, in collaboration with Participation Architect Jane McGonigal and Gamemasters Dee Cook, Marie Lamb, Michelle Sendergauf, and Krystyn Wells. The small staff provided a Web site platform and an ongoing backstory, injecting new circumstances and events into the ongoing narrative. They supported the contributions of user generated content by approximately 1,800 people in real time, and gained wide distribution, with over 60,000 viewers via the Web.

Alternative reality gaming is a genre that can be highly addictive to users, composed of an amalgam of interactive digital storytelling, online community, and treasure hunt. The Web site, live and continually refreshed for the duration of the game, featured a reality dashboard that was updated daily with socioeconomic metrics such as fictional gas prices and fuel shortages. The Web site linked

to contributions by participant netizens, including videos, blog posts, Web comics, podcasts, and other user generated content documentation of their imagined life in the post-oil world. The gamemasters who solicited these contributions played characters featured on the Web site, and were also available to interact with game players via phone and e-mail. They curated the user generated content contributions and awarded prizes for excellence, ranking them to encourage participation and content quality.

The game was announced to the public on March 2, 2007, via a teaser Web site. A countdown appeared two weeks before the game began. When the game started, the Web site totally changed and provided broad-brush details of the peak oil crisis. Players from diverse backgrounds from all over the world were recruited from a solicitation that went viral. They represented a broad demographic of people interested in the issue for a variety of reasons. Players of all ages hailed from the United States, overseas, the oil industry, and grassroots communities. These producers filled in the details and shaped the game's direction, posting contributions using Web 2.0 tools and media. The gamemaster characters documented the lives of their characters and commented on player stories on a community blog and individual blogs, as well as through instant messaging, chat, and Twitter.

These producers, who formed for a time a social issue online community, initially provided letters, videos, and podcasts describing family disintegration, violent crime, government inaction, and rioting mobs. Eventually, with guidance from staff gamemasters, the focus shifted as contributors began to devise and contribute constructive ideas for living a less petroleum-dependent life. Designer Ken Eklund calls *World Without Oil* the world's first serious ARG. It was a serious game because its players focused on an issue of gravity, preparing for life after an oil crisis. As an ARG, it was open-ended, driven by human intelligence, and revolved around a splintered narrative that players worked together to solve. In ARGs, designers—often playing characters—create and guide the scenarios, but other participants often choose where to take the plot. This was the case for *World Without Oil*. Crowdsourcing thus played an enormous role in the success of the project.

ARGs usually not only involve the players with a Web-delivered narrative, but also connect them to the real world. They often result in community because many games can only be mastered through the collaborative efforts of multiple players who find it necessary to engage with the real world to find clues and other materials. ARGs are usually free to play; they are notably not as profitable as many other digitally delivered games. Thus, ITVS's sponsorship of *World Without Oil* was crucial to its success. Reciprocally, *World Without Oil* helped ITVS to meet its mission of developing exemplary interactive digital media productions through its Electric Shadows Initiative. Electric Shadows projects present independent media makers' visions related to arts, culture, and society to the public via the Web. Meeting the ITVS goal of advancing civic participation and creative risk taking, the Electric Shadows Initiative has funded six online projects since it began in 2002. These projects, which have garnered a number of national and international awards, utilize innovative forms to elicit interaction from its viewers. Personifying innovation in nonlinear storytelling, and a collaborative learning experience and social issue game, *World Without Oil* serves as a model for digital public media.

The Writerguy Team that developed *World Without Oil* and harnessed the contributions of its producers included some of ARG's most experienced gamemasters. Ken Eklund, the project head, worked as a game writer and designer for over 20 years, with credits on over 24 games and many Internet-based educational projects prior to his work on *World Without Oil*. Jane McGonigal, participation architect, has been a game designer at the Institute for the Future in Palo Alto, California, and was lead designer at 42 Entertainment, notably for *I Love Bees*, an award-winning alternate reality game. In fall 2006, McGonigal was credited as one of the top 35 innovators changing the world through technology in the *MIT Technology Review*.

While the game finished in June 2007, its legacy continues. The Web site has been transformed into an immersive archive of the game, with substantial content repurposed for educational use. The Web site features guided tours of player-created content, lesson plans for teachers and students, and a seven-minute behind-the-scenes video. Designer Ken Eklund maintains a blog to

provide project updates such as the awards that it has won. *World Without Oil* won the Award for Activism in the 2008 South by Southwest Interactive Conference, a Special Mention in the Environment Category for its contribution to humanity in the 2008 Stockholm Challenge, an Honorable Mention for the Prix Green Award for Environmental Art at the 01SJ 2008 New Media festival, and it was an awards nominee in the Games category for a 2008 Webby Award.

Writers and Social Media in Politics

Political writers adjust to social media in adapting to new audiences, genres, media platforms, and ethical dilemmas. These are interrelated because audience expectations change as technology allows authors to publish more cheaply and frequently, with more audience participation, and more integrated media. This has allowed political writing via social media to become a widespread activity; however, scholars debate if this saturation has net positive or negative effects for social participation in politics. Adaptability is also essential in this regard, in that unevenness in skills and the capacity to adapt to online formats exacerbate inequalities

among writers, even as social media offer a possibility for widespread democratic practice.

Audience and Opportune Timing

Writing always engages the capacity to target an appropriate message to a particular audience. This rhetorical capacity—the ability to persuade a given audience by imagining and judging the artistic means to persuade—alters with social media. Audiences expect opportunities to participate in the message more directly, minimally through direct feedback and reposting. Thus, the proximity between authors and readers has greatly diminished. Following the Twitter feed of an author after sale of a new e-book, joining and participating in a Facebook group that engages a political celebrity, or simply commenting on a news story are among the most widespread of activities in the contemporary moment. Under conditions of proliferating texts, connecting and sustaining readership becomes a primary skill. Audiences can click down an endless road of links, and traffic starts and stops at only the most convenient of sites. Algorithms and search tools navigate to the most convenient, cross-listed, and relevant starting point. Thus, finding appropriateness often means an apt keyword, a previous fan base that checks regularly for updates, or a title that includes unique, yet comprehensive words to summarize the piece.

Scholars group the types of social action that take place online into three realms of digital participation. First, there is user-to-system activity, in which writers are interacting with the Internet as a system of catalogued resources: searching terms, clicking hyperlinks, or downloading and utilizing applications. Second, there is user-to-document activity, in which writers add content to the Internet—content that can be further subdivided into blogs, wiki or encyclopedia edits, news posts or essays, or any other content. This, of course, is what most people would consider as “writing,” but it is important to remember that even historically writing was a human endeavor that could not be reduced to the moment of pen-on-paper, but also involved time in the archives or conversations of others. Third, there is user-to-user activity, such as chatting or exchanging comments on a post or news feed. The genres swiftly break down because documents are usually highly interactive,

and audiences expect them to be so. Thus, encyclopedia entries will have forums to exchange comments about editing; blogs will have comment sections that will spur the writing of other posts in reply; and online polling will lead to the publication of an article with poll results.

These digital genres of writing form a continuum. On one end is the single comment made before moving on to other links or disengaging from the Internet and moving to offline activity. On the other end is the development of close knit networks or communities in which public discussion is sustained by sufficient emotion, forming long-term identities and relationships in cyberspace. Whichever of these one takes as the paradigm determines much about how one thinks about writing online. The fluidity between the two is a hallmark of digital writing. Never before could one have so many happenstance readers who stumbled upon a document or forum just by following a chain of references. On the other end, social media forge a unique capacity for a community to stay engaged against all barriers of place, disparities of living condition, and diversity of beliefs or demographic characteristics. Audiences often have the luxury of either, and writers adapt to those possibilities.

Privacy, Identity, and Public Attention

Even if the connection with audiences can sometimes be quite sustained and communal, users do not have access to each other's prior reputations in the sense of older communities of honor, in which ethos could be crafted throughout a lifetime of interaction by the constraints of geographical or familial ties. Rather, a particular text must, more than ever, create the web of culture, purpose, motivation, and reasoning processes for communicating that more bound cultures could take for granted.

One of the ways this happens is for writers to construct identity by means of character appeals. Identity is often enacted and leveraged in short, ephemeral online acts, but ethos extends beyond individuality and into structure of the Internet, formats, traditions of thought, and aspects of trope and genre. Users often judge site ethos by factors such as visual design and layout, information structure, and usefulness, rather than by who wrote site content. Powerful interests, whether

profit or vote seeking, can also craft better identity appeals by collecting data on individuals as discrete and quantifiable entities. Companies collect information from census and registration information, purchase history, shopping activity, or political donations to target very particular demographics. Writers with connections to these sources of data use such information to craft appeals to narrow target audiences, a practice sometimes called narrowcasting.

Online writing makes more acute the sense that one is weighing into a conversation already begun. Writers on comment forums will often write their way into conversations, marking their entry with an identity performance that precedes or encompasses public argument. Announcement or recognition of personal traits (e.g., partisan identification, shared health concerns, economic interests, or gender and sexuality concerns) can serve importantly as identity creation to position arguments. This digital constitution of ethos demonstrates awareness of authorial personas as shifting and never absolute or complete. This is an important move in an environment in which otherwise, appeals lack human embodiment and other markers of presence and social roles. Whereas in the past, this process would be mostly unconscious as one moves between the spaces of home and work, social media allow for the realization that such shifts can be rapid. In regard to politics, users can even take multiple positions on key issues and regulate what sorts of appeals go to which user groups. Somebody who is out of the closet to friends only might advocate for gay marriage by hyperlinking or making advocacy arguments on Twitter, even as the person remains closeted to family on Facebook.

In addition to the social work that such identification allows, it also helps to create rhetorical immediacy. Plato's call for soul-to-soul communication between friends as a political project takes the form of readers "friending" their favorite writers, knowing moment-by-moment their life routine, thoughts, or private escapes. Audiences can feel "in the room" as members of Congress tweet responses to a State of the Union speech. This simulation of intimacy has led to an erosion of previous decorum, as sound bites (audio and textual) flood media coverage for further circulation and generation of content for public

judgment. Profane, bitter, or ironic comments circulate far and wide, creating a market for notoriety through quasi-offense. Thus, all of this circulation erodes previous barriers, as it creates a culture of spectacle in which one acts as if private comments mattered for the public good.

One unintended consequence of such an increase in circulation is the rise of irony, humor, and parody. The appeal of ironic political coverage in writings such as *The Onion* provides readers and political writers the type of discursive exchange necessary to distance from politics with comedic perspective while allowing tragic proximity through advocacy media at other times. Another unintended consequence is the movement away from on-site writing and reporting, or investigative writing sponsored by mainstream media. The circulation of sound bites, written or spoken, and punditry about meaning and contextualizing take the central national conversation. In such banter, the norms of objectivity also shift toward agonistic disagreement, rather than consensual reporting or balance. Mainstream news writing and reporting still set much of the agenda for political news, even as freelance and undercover journalists try to enjoy those profits or reputations. Partisans embedded in social activism or other news spectacles also try to frame the message more than in the past. These unedited accounts from the ground up form a new potential for writing from below. Protest leaders with a Twitter account or workers inside a firm or union boycott can achieve strong publicity through such writing, as long as interests in power do not cut off access, and the context for such writing has been set within a dominant news narrative that generates necessary attention.

Convergence

Good writers have always imagined audiences to hone their appeals. Writers of some regard even dealt with attracting the attention of geographically and culturally diverse audiences. The Internet expands that kind of thinking to nearly all Internet users. Richard Lanham, an important and influential expert on writing and rhetorical style in the digital age, argues that the Internet is a pure case of an attention economy. It is the chief resource cultivated, and its scarcity leads to all manner of persuasive negotiations. In the

realm of politics, campaigning is nearly incessant, issue advocacy creeps into every outpost of Internet activity, and politics news and opinion drives some of the largest numbers of online users of any sort. Attention is in such demand that writers often turn away from a general public as audience, instead seeking out counter-publics: groups positioned at odds to the dominant attention group. Communication in these counter-publics, either in content or mode, creates alternative beliefs, lifestyles, social activities, or online performances. This oppositional attention can be especially important and potentially liberating for minorities marginalized by dominant mass media.

With publics or counter-publics, writers must cultivate attention. E-mail lists, mass scheduling and reminders, and synchronous online events (such as live chat sessions or video conference) all help sustain participation. Some social media and portable devices help with this process by keeping users connected to a feed, subscriptions, or followers, preventing users from clicking a series of links that send them further and further into more particular and individualized paths of reading.

The word *public* is also worthy of consideration. Historically, spatial limits marked the realm of politics from that of private life or professional life. Political actors thought about entering legislative halls, courtrooms, or even taverns as public spaces. To do so, speakers would leave behind matters of merely personal interest, such as private finance or relationship advice. Never as tidy as this even in antiquity (see, for example, Cicero's private correspondence), one of the central aspects of political writing in modernity, after the establishment of printing press, was the slow collapse of any such divisions. Public letters, for example, were often printed with an explicit audience of a king, governor, religious leader, or other institutional figure. Yet, the intended readership could be vast, including what we think of as "the public," however constituted. In addition, the way such letters were signed is of interest. Some were anonymously written, some used pseudonyms, and yet others used names, titles, and official institutional affiliations. Each move could be incredibly significant rhetorically—often diminishing, highlighting, or concealing political agency or authority.

Social media follow in that rhetorical tradition. Writers can easily publish anonymously,

offering protection for minorities and those dissenting from power, while also sheltering some from negative repercussions from their statements. Internet "flaming," the practice of writing incendiary comments, can mostly be done at leisure, without any worry about diminishing long-term ethos. It is sometimes possible to track down IP addresses, just like publishers and news editors can give names in extreme cases of danger. However, a set of safeguards put in place help protect that anonymity. Writers and society more generally will continue to struggle with what degrees of anonymity and pseudonymous publishing will be tolerated in regard to political speech. The central issue regards protection of dissent without slipping into intolerable shouting, or what many political elites today call more broadly "incivility."

Social media also confound notions of privacy and publicity. Partisan memes circulate to denigrate a party or perspective, build identification, and move opinions on an issue. But of course the audience for these are often friends and family, and such posting can be quickly alternated with family pictures, current status postings, or religious or philosophical proverbs. The idea of separating public, private, and professional activities as distinct quickly erodes in such spaces. This also has a reciprocal effect, on the heels of 24-hour news and other media changes, of making public scrutiny of political leaders very personal. Politicians' private actions and posts are open to public access and scrutiny, much like celebrities, whose lives are commoditized by revealing intimacy.

Hybrid Political Texts

In this environment of boundary blurring, writers respond by generating hybrid genres—forms of writing that garner attention by the skillful mix of previously distinct patterns of privacy, publicity, and sociality. Intimate campaign ads are made specific to a particular person. Political prose in blog writing integrates personal narrative and appeals to particular friends, like the public letter of years past. Anonymous comments take the form of oral deliberative rhetoric, enumerating argumentative points to weigh into controversy, but doing so privately, without the transparency of public action.

Such hybridity is also created by the integration of advanced Web platforms and design. The increasing ability to edit the visual seamlessly with text creates a world in which writing is rarely, if ever, a solely textual experience. With WYSIWYG (what you see is what you get) technologies, clarity and sophistication through other media incurs very low technical barriers. Free software and editing tools available to most Internet users give results that are incredibly fast. Companies move into even more leading-edge technologies for design and publicity, generating a constant competition for upgrades and professionalism. Thus, even while there are radical advantages over just a few years previous in simple digital upload and development, revenue streams can still buy hits and generate ads that are essential to overcoming the clutter of most social media.

Henry Jenkins argues that this competitive environment for attention leads to “convergence culture,” as boundaries blur not only between genres and modes of appeal (e.g., text, audio, and visual rhetorics), but also between content producers and receivers across media platforms. Writing, in this world, becomes co-creative design. Illusions of a stable and finished “text” by a solitary “author” become even more attenuated, bringing postmodern critiques of modern thinking and writing into reality.

Scholars of rhetoric in social media also note a return to classical notions of rhetorical invention, over modern ideas about new, original, or authentic writing or voice. That older rhetorical paradigm saw all writing as a productive recreation of other ideas, with knowledge content not the proverbial lightbulb in the mind of an author, but rather a careful set of choices regarding appropriateness for sampling and reusing content of previous writers. Style and delivery were also understood not as something absolutely unique and originating with the individual, but as communal and mixed from models and training. Form and content in social media are frequently constrained by the platform, but also share much from one another through clever borrowing, or witty and ironic appropriations of prior political texts.

Modern copyright laws struggle to keep up with this sea change. Especially in regard to private property and profitability, but even about ethos and reputation, questions continually arise

as to what “counts” as intellectual theft and unreflective mimicry, or alternatively, educational enhancement (handled under “fair use” doctrines) or protected political speech (such as political dissent that borrows a political song, speech, or logo for new purposes). Within that continuum are grey spaces that call for legal interpretation and questions about the threat of this convergence culture to individualism, writers’ ownership of their words, and private-property capital.

In short, writing for social media involves a series of collapses that lead to new demands on writers for hybridity, integration, and negotiation of reuse. As opposed to the public sphere premised on certain procedures and normative ideals separate from private or technical matters, this social media convergence culture thrives on destabilization of dominant written forms. This shifting is likely to diminish as the technologies age. For the foreseeable future, though, social media writing occurs at a cultural position that has the potential to destabilize settled political power, challenge older patterns of partisan relationships, and increasingly integrate and disintegrate alliances across borders.

The Ethics of Political Writing and Social Media

Chaim Perelman, a Belgian Jewish philosopher writing on the failure of philosophical reasoning with Nazi Germany and fascism, predicted the need for a dual sense of audience for reasoned argument. One audience, Perelman claimed, persuaders had always taken as central: the particular audience for whom reasoning could be adapted to gain adherence to specific action. On the other hand, Perelman wrote, it would be necessary to imagine a universal audience of all reasonable people deemed fit to judge the text. This sort of imagining of intended audiences would help prevent the short-circuited reasoning that tried to appeal to universal political values (e.g., patriotism, solidarity, peace, progress, or prosperity) on the back of traditional or manufactured prejudices of the particular group.

The Internet, again, makes this to some extent a reality. The ease of copy-and-paste, circulation between points near and far, and news produced by hyperattention all drive a sort of universal check on speech. Diplomatic writers are

increasingly accountable to public scrutiny as secure documents leak. Posts intended to be limited to particular groups, such as neo-Nazi or neoconfederate groups, become condemned by a national audience who might have never seen such speech before. Even everyday political writing and speech can be held to a degree of scrutiny by nightly recirculation of sound bites, late night comedians, or satirical news or memes.

At the same time, dangers are more widespread. Racist propaganda in one nation can lead to crimes and mob action in a distant village or nation. More common than these chain reaction events are the millions of ways that writers fragment readers into narrower attention groups until less is left in common. Even beyond the “bedroom culture” of the 1990s, in which each member of the household might have his or her television with an increasing variety of channels, every family member might now have social media and mobile technologies. Writing on these platforms can be segmented to even more particular users. This fragmentation can lead to new tribalism. Fundamentalist religious groups, hate groups, and radical anti-authority groups can quickly and quietly gain adherents. Writers can quickly convince a particular audience that their particular view of the world is the only right one. Thus, while some writers pull toward “politically correct” speech that can appeal to a universal sort of audience, a backlash toward stylistic and ideological deviance occurs that takes advantage of split attention and the decline of conversations that might spur cognitive dissonance and moderate views.

Another danger at work is the sense that political writing through social media in and of itself is sufficient as political action. The possibilities at the dawn of this digital era are so great in regard to searching out, indexing, contributing, and reposting content that writers begin to feel that this intervention is sufficient. In some cases, with all the pressures of life, this may be true: in some controversies, a small shift in opinion among one’s friends may be the endpoint for sustainable public action. On the other hand, scholars worry that this limited sense of political action erodes a broader set of strategies available to the public—especially those that involve physical intervention in the promotion of the public good. The integration and rapid spontaneity of writing with social

Canadian novelist Cathi Bond is an example of a writer who engages with her public using both old and new media tools, including radio broadcasting and cohosting podcasts focusing on trends and technology on a Web site called The Sniffer.

protest, as happened in social movements from the Arab Spring to London and Wisconsin, show the potential of the productive uses of the technology and writers’ capacities to spur action.

Those are fairly limited instances among otherwise strong forces toward the status quo, though, as well as increasing gaps between citizens and government officials. “Sharing” and “liking” suffice as the extent of Internet usage. Meanwhile, accountability becomes more diffuse and political leaders increasingly search for donors, rather than opinions in social media. In the guise of potential emancipation, social media allow people with scarce time and energy to satisfy civic duty with momentary attention. This escapism allows one to sense that the agreement of small likeminded audiences results in meaningful change when in reality, a world of consultants, pundits, think tanks, and other writers continue to control the dominant political and media narratives. Quantity of texts can help, but offer little final cure when such power imbalances are at play.

Major questions arise as to the skill level, adaptability of typical citizens to this online writing environment, and education priorities. The Internet may pose a risk of excluding a few without access, and in the short term, form a type of age discrimination. As math and science education increasingly become the priority in a

technology-driven world, it is unclear that citizens will have similar access to education to sustain online arguments and become literate producers and consumers of convergent and hybrid content.

Writers have an obligation to take on these issues as they enter into political controversy. Most scholars are optimistic about the chances for robust deliberation through such writing and textual circulation, even while they realize that new versions of republican and consensual models will need to buffer against extreme agonism. New competition for attention and decentralized exchange through an unquantifiable number of texts will erode chances for compromise or consensus as a means to good governance. Transparency, accountability, and freedom of dissent will remain in a more tenuous balance as writers pursue their craft and increasingly set the agenda for national discourse. Writing and social media have the capacity to entirely change the political process, but that shift must be slow and careful, considered against technology breakthroughs that falsely seem to offer immediate intimacy and liberation.

Youth Engagement

Youth engagement refers to the political and civic activities performed by young people, both online and offline, which connect them to various aspects of public life such as voting in elections, doing community work, joining social movements, and signing electronic petitions. Within the social sciences, 30 years old is generally accepted as the defining boundary between young and older. Thus, youth engagement refers to participation by teenagers and young adults. Because in most countries the diffusion of social media has been led by high school and college students, understanding the uses and effects of social media on youth engagement has become a hot topic for scholarly research on how to reconnect younger citizens with the public sphere of politics and civic activities.

An important attribute of youth engagement is that the types of activities that fall within the concept are constantly evolving. Thus, some scholars consider acts such as news consumption or informal political discussions with friends as important components of civic and political engagement. Others, however, prefer a narrower definition, exclusively equating youth engagement with behaviors that have the clear purpose of achieving a civic and/or political goal (e.g., voting). In this case, information consumption

and public expression are regarded as antecedents, not components, of engagement.

Political Versus Civic Engagement

Regardless of the breadth of activities that fall under the rubric of youth engagement, there are important differences between political and civic forms of engagement. Political engagement refers to behaviors adopted by citizens aimed at shaping government and policymaking. While voting and participation in elections are regarded as typical forms of political participation, social media have expanded the array of political activities conducted by youth. For instance, contributing to political blogs, writing political messages in social network sites, and forwarding online videos of candidates have been identified as new forms of political participation.

The term *civic engagement*, on the other hand, denotes voluntary actions taken to assist people outside one's family and circle of friends, such as donating to charity, as well as activities to improve the conditions of the local community, such as joining neighborhood associations. Conceptual differences notwithstanding, civic and political engagement can influence each other. For instance, research on the civil rights movement of the 1960s in the United States has demonstrated that participation in civic youth organizations during adolescence can be a powerful

Students at McGill University in Montreal, Canada, taking part in the creation of “vote mob” videos to demonstrate their interest in politics on April 14, 2011, in response to low voter turnout rates among Canadian youth. The videos of hundreds of students rallying to show their interest in political engagement were then posted on YouTube.

predictor of adult political behavior 25 years later.

Youth engagement is regarded as a key element of the transition between adolescence and mature adulthood. During childhood and adolescence, people become aware of political institutions, social issues, and larger communities; learn facts and concepts related to politics; and begin to practice active citizenship by volunteering, belonging to groups, consuming news media, and discussing issues.

Compared with the older generation, youth engagement tends to focus on local projects instead of national causes; their activity is more informal; and their means of acquiring information are more Web-based. Therefore, many observers have noted that conventional civic and political organizations face shrinking memberships precisely

because younger generations are not inclined to enter into formal membership relations. As for politics, it is argued that youth care more about specific aspects of politics, but less about general politics compared with older generations.

Differences in the ways that young and older generations engage have been at the center of a debate between the common view that advanced democracies, especially the United States, exhibit declining rates of engagement; and the alternative view that sees engagement as shifting from elite-driven activities (e.g., donating money to a candidate) to self-driven forms of participation (e.g., writing political comments on Twitter). Social media, with their emphasis on user-generated content and self-expression, are particularly amenable to the latter perspective of youth engagement.

The Affordances of Social Media

The literature on political behavior has demonstrated that, at an individual level, motivations, skills, and opportunities are necessary for teenagers and young adults to civically and politically engage. In this sense, social media can play a pivotal role in promoting youth engagement.

While young people may lack the psychological or material resources to engage in civic and political activities, using social media can promote participation by lowering the costs associated with acquiring mobilizing information and increasing youth's political efficacy. Social media has also broadened the ways by which youth can express political or civic concerns, such as when college students who belong to an on-campus student organization create a blog or Facebook profile for it and connect with similar groups from other universities or countries. Social media may also expand people's social networks because they provide additional opportunities to contact friends who are physically separated, and promote social interaction with acquaintances and strangers. Social media also influence the ability to express political views and build a political identity, such that members of less powerful groups can express views that might have otherwise been punished or sanctioned by more powerful parties. As political and civic organizations become more technologically savvy, many offline forms of political participation, such as donating money to organizations and petitioning authorities, can quickly and easily be conducted online.

Unlike traditional media, social media rapidly and efficiently distribute a high volume of information. Because easy access to information is an important, although not always sufficient condition for engagement, social media may facilitate news seeking for users and increase the possibility of political discussion and engagement. In developed countries, statistics show that although most young people encounter some online news, most come across it casually or accidentally in the midst of other pursuits.

Also, social media enhance young people's personal expression on individual bases. These civic trends include the rise of more personally expressive cause-oriented politics based on lifestyle concerns such as consumer behaviors, and the emergence of direct-action protest networks

in a variety of local to global arenas. While time and place limit physical interpersonal communication, social network sites make it up as an interactive-based application for online discussion. This creates opportunities to learn mobilizing information, ponder news or public issues, and reach common understandings, all of which are key antecedents of active engagement.

In particular, the interactive feature of social media may amplify the effects of political expression because they readily allow one's expression to be viewed and shared with many people simultaneously. Young people's expressive potential has been transformed; individuals are now in a position to post, at minimal cost, messages and images that can be instantly viewed by global audiences.

However, not all groups of young people do benefit equally from the affordances of social media for engagement. There are important gaps in social media use and civic or political participation across socioeconomic status, gender, and racial/ethnic status. The existence of these gaps are a strong reminder that whatever the affordances of social media, the effects of these digital tools on youth engagement are contingent upon the specific ways that young people use them.

Existing research shows that using social media for surveillance and news acquisition is positively associated with various forms of political activity, whereas using social media solely for the purpose of private entertainment and diversion will most likely distract users from civic or political engagement. Certainly, social media can be purposefully used to search for news (e.g., becoming a "fan" of a news network on Facebook) as well as a source for incidental exposure to news (e.g., browsing the profile of a friend on Facebook, and stumbling upon a link to a story produced by a news network). In either case, learning can take place, which is an important antecedent for behavior.

Using social media for expressing political opinions can also lead to engagement if these opinions trigger online conversations about public affairs, which research has found to be as conducive to political engagement as interpersonal discussion. Also, the textual nature of most communications within social media may result in communications that are more goal-oriented than

face-to-face discussion. If this is the case, then discussions on social media may be quite efficient at mobilizing young people to participate in political and civic activities.

Social media can also lead to engagement when youth use these platforms to search for and join political and social causes. Once users connect to organizations online through social media, these organizations can then invite their followers to mobilize for a cause. This explanation focuses on the possibility of finding mobilizing information on social media platforms, either by direct exposure to messages and profiles of social movements, NGOs, and other interest groups, or indirectly through incidental exposure.

Thus, information, opinion expression, and joining causes are specific ways in which young people who use social media can become engaged. Then, again, absent these uses, the likelihood of social media use leading to engagement is diminished.

Alternative Sources of Engagement

Social media, of course, are not the only—or, for that matter, the most important—source of youth engagement. The literature on political socialization conceives youth engagement as the result of multiple influences operating simultaneously. Civic training in adolescence can influence adult behavior, within which school as an institution plays an important part. Civic instruction is commonplace at the high school level, though it varies from current events requirements in classes to mandated service work in the community. Existing evidence shows that young people who volunteer in high school and college are more likely than their nonvolunteering counterparts to engage in volunteering, community activities, and other forms of civic life as adults. Involvement in after-school activities also plays a role. Individuals who were active in school organizations as teenagers are disproportionately more involved as adults, even when the impact of later influences such as marriage, children, and advanced education are taken into account.

Besides schooling, many of the important lessons for engagement are learned at home. Young adults who grow up amid regular political discussions are much more involved in a host of activities. For instance, evidence collected in the United

States show that among young people who are eligible to vote, 38 percent of those from homes with frequent political discussions say that they always vote, compared to 20 percent of those without such dialogue. Similarly, more than one-third of those who often heard political talk while growing up are regular volunteers, compared to just 13 percent of those raised in homes where political talk never occurred. By talking about politics, families teach their children that it is important to pay attention to the world around them—and take action.

Parents and guardians, even siblings, also provide critical role models for civic behavior as well. Young people who were raised in homes where someone volunteered are also highly involved—joining groups and associations, volunteering, wearing buttons, or displaying bumper stickers at rates higher than those who did not grow up with such examples. Similarly, youth with engaged role models are also more attentive to news of politics and government, and are more likely to participate in boycotts or buycotts. Both of these influences are significant, even when demographic and other factors are taken into account. In addition, research has shown that attending religious services provides effective training for civic engagement, because youth come into contact with opportunities to volunteer and become involved with their communities. Therefore, the influences of social media on youth engagement can also indirectly operate by having an effect on these other, alternative sources of engagement.

YouTube

YouTube, the video sharing Web site, was launched in June 2005. At the time, it was only one of a number of competing Web sites and services aimed at making it easier for users to participate in widespread content sharing, including images, photos, and video, which was proving to be an especially tricky type of material to efficiently send over the Internet. YouTube offered a free, simple, and integrated interface that minimized the level of technical knowledge required of users. The site also provided basic community functions, such as the ability to link to other users as friends and easy ways to embed uploaded videos to other Web sites; this allowed users to easily share videos across the Internet. In October 2006, YouTube was acquired by Google, and by early 2008, it was consistently rated by various Web metrics services as one of the top 10 most viewed Web sites globally.

As YouTube settled into the basic configuration it still uses today, it offered many key features that were appealing to users and have helped lead to its position of dominance in the digital video domain. One of the most important factors in YouTube's success came from the site's shift in concept, from that of a Web site for personal video storage and sharing, to that of a platform for social expression. This concept change positioned YouTube within the user-led revolution that was indicative of the emerging Web 2.0 environment. YouTube also capitalized on key user features, such as video recommendations, e-mail

links that enabled easy sharing, an embeddable video player, and social networking functionalities such as commenting. These features helped YouTube to emerge into multiple roles in the digital video environment, including those of a high-volume Web site, a broadcast platform, a media archive, and a social network.

The YouTube Effect

YouTube is the premier video sharing Web site. Web metrics services estimate that the site accounts for roughly 37 percent of all Internet traffic, and its continued and rapid growth makes keeping up with usage statistics difficult. By early 2011, YouTube had reached more than 1 trillion views, equating to roughly 140 views for every person on Earth. By May 2013, the site boasted over 1 billion unique user visits per month, who spend an estimated 4 billion hours watching videos; the average user spends between 15 and 25 minutes on the site per day. Roughly 72 hours of video are uploaded every minute, and more video content is uploaded in a 60-day period than has been broadcast by the three major U.S. television networks in the past 60 years.

YouTube is localized in 43 countries and functions in 60 languages, with an estimated 70 percent of the site's traffic coming from outside of the United States. YouTube also has a significant social media reach, with roughly 500 years of video watched via Facebook every day and over 700 YouTube videos shared via Twitter each minute. YouTube is accessible on over 350 million mobile devices; more than 10 percent of global views come from these devices, and three hours of video are uploaded to the site through mobile devices every minute.

YouTube and Politics

YouTube emerged as a significant force upon the U.S. political scene in 2006, when a video featuring a gaffe by a senator seeking re-election was caught on camera, uploaded to YouTube, and went viral. The video quickly gained momentum as both online and mainstream media outlets picked up the story. The ability for this political misstep to reach hundreds of thousands of viewers and attract the attention of the mainstream media was an early indicator of the potential political power of YouTube.

Although some videos during the 2006 election caught the attention of users and the mainstream media, it was not until the presidential election season of 2008 that YouTube became a serious campaign battleground. YouTube radically altered the political ecosystem and played a critical role in helping candidates reach audiences and mobilize voters. During the 2008 election, roughly 39 percent of voters reported watching at least one political video online, official candidate videos received over 200 million views, and videos created by individuals or groups not associated with campaigns were viewed over 1 billion times.

YouTube has been instrumental in changing the political communication landscape in the United States. Prior to the 2008 election, the majority of the political videos on YouTube were “gotcha-type” videos or parodies, but this soon changed as the public and candidates began to embrace the Web site as a platform for serious political messaging. Campaigns began to utilize YouTube to reach audiences with videos of speeches, rallies, and political commercials. YouTube became a viable method for candidates to engage the public through videos, many that were viewed by millions, without the direct influence of the mainstream media or political parties.

YouTube has provided new ways for politicians to reach audiences, particularly younger demographics, and has allowed lesser-known candidates to have a platform. YouTube has also been credited with increasing the accountability of candidates, elevating the democratization of information, minimizing political artificiality, and increasing transparency. No longer can politicians ignore or deny previous statements, as recorded and often unscripted moments have a way of taking on a new life in the YouTube domain.

In just a short time, YouTube has become a necessary mechanism in political communication. Multiple candidates, in races both large and small, including President Barack Obama, have announced their candidacy via YouTube videos; mash-ups and user-generated political videos have been seen by millions; the public was invited to participate in political debates via the CNN-YouTube Debates; and political speeches that may have only been seen by the audience in

attendance have become some of the most viewed political communication ever. In 2011, more than 500 candidates for political office and roughly 92 percent of House and Senate members had official YouTube channels. The Obama White House embraced YouTube as a mechanism for communication by creating the White House YouTube Channel, which posts an average of 17 videos per week, such as the president’s weekly radio addresses and interviews with Obama generated from questions submitted by YouTube users.

YouTube and Participatory Culture

Through accessible digital technologies and user-generated content, YouTube has emerged as a site of participatory culture, one that has shifted the power relationship between politics, media industries, and consumers. YouTube functions as a site of cultural commons and political listening among users. This environment is not bound by the traditional confines of political communication; instead, it functions as a mediating mechanism for cultural and political citizenship that is created and disseminated by ordinary citizens. Via YouTube, individuals, regardless of location or time zone, can engage in political discussion and online videos passed virally between users. They are important rhetorical and persuasive artifacts.

The commerciality of YouTube has increased the possibilities for participation for a much broader range of contributors than ever before. Simply put, YouTube has become the world’s largest town hall meeting. Through YouTube, a new meritocracy for political information, free from the gatekeepers and agenda setters of traditional media, have been able to connect with politicians, parties, candidates, and other voters in ways that were never before possible.

YouTube also functions as an important fact-checking platform for political information. If users come across information that is incorrect or misrepresented, they are highly likely to draw attention to it and discuss it virally, which essentially requires candidates or campaigns to respond. In the YouTube environment, candidates, campaigns, and the mainstream media no longer have total control over political messages, which has changed the ways that candidates must campaign.

Criticism of YouTube's Political Impact

Despite the widespread adoption of YouTube by politicians, the role it has begun to play in politics has ignited criticism. Critics argue that the culture of YouTube has resulted in the death of spontaneity in political discourse. It has created a mediated environment where candidates can no longer experiment with and refine campaign messages and are worried about having a “gotcha” moment captured and posted online. These factors have led to more scripted discourse and have removed some of the richness from political discourse. The long-term political relevance of YouTube has also been called into question. Critics suggest that large viewership numbers are not necessarily relevant because many users are young and not highly politically engaged, and campaigns often use strategies to overexaggerate the reach of political messages.

Conclusion

YouTube has substantially impacted politics in the United States. With metric services estimating that within the next decade, up to 90 percent of all Web traffic will be video-related, it is likely that YouTube's role in political communication will continue to gain significance.

YouTube Politics Channel

The YouTube Politics Channel, launched in October 2011, is a dedicated channel within the YouTube platform that serves as a hub for locating and accessing political videos, campaign messages, debates, news broadcasts, and parodies regarding the 2012 presidential campaign. The various features of the Politics Channel provided analytical data for assessing candidates' popularity, methods for tracking the latest political videos, opportunities to connect with candidates' personal YouTube channels, and platforms for users to communicate their opinion of the campaign. The primary focus of the Politics Channel was the 2012 presidential campaign. However, the channel also included videos beyond this scope by posting videos from other political races and content from various political activities, such as the Tea Party and Occupy Wall Street movements.

The Politics Channel served as a mechanism in Google's attempt to solidify positions both as a dominant provider of digital political content and as a go-to source for political news and information. In response to the public's increasing appetite for gathering political information online, and campaigns' increased use of the Internet as a platform for framing and distributing messages, the Politics Channel was developed as a one-stop online destination for political information related to the 2012 presidential primary and election season.

Videos distributed through the YouTube Politics Channel were cultivated from a variety of sources, including candidates' official YouTube channels and Web sites, media outlets, and everyday citizens. A third-party outlet was also employed to search and monitor user-generated content on a variety of social media platforms; videos that were found to generate significant attention were then distributed via the Politics Channel. This allowed users to not only easily find videos produced by campaigns and media, but also provided access to unscripted political moments captured by ordinary people. The goal of the YouTube Politics Channel was to provide a holistic view of what politics look like in the YouTube environment.

Features

Through multifaceted functions, the YouTube Politics Channel attempted to connect users with all aspects of the presidential campaign, including news stories, campaign ads, debates, parodies, and speeches. The Politics Channel utilized the flexibility of the online environment to continually adapt content and maintain the channel's relevance throughout the election cycle.

During the primaries, the channel included multiple features that allowed users to follow and connect to the candidates. A prominently featured graph provided a running tally of the primary candidates' popularity in the digital video domain. The graph tracked the number of video views, YouTube search queries, subscribers, and video shares by candidate. A "meet the candidates" section allowed users to view popular videos, find statistics for each candidate, and directly navigate to candidates' individual YouTube channels. The candidate "dashboard" offered options for users to receive regular updates and videos from campaigns. Finally, a "hot political videos" tab linked to each day's top political videos from across the political spectrum; videos were a range of user-generated news footage and campaign videos.

During the conventions, the Politics Channel adapted its content to more specifically focus on the conventions, eliminating many of the features prominent during the primaries. The "conventions 2012" tab provided videos of all of the speeches broadcast during the conventions, as well as behind-the-scene candidate videos, news segments, and audience reaction videos. A feed tab, utilizing a really simple syndication (RSS) feed, a method of distributing links and syndicating content, was also added. This feature allowed users to quickly navigate to the most current videos uploaded to the channel and to videos linked through other YouTube channels and media outlets.

Following the conventions, the channel adapted its content to focus on the final stages of the campaign. Through the "elections 2012" tab, users could watch "What's On Now," spotlight videos highlighting timely and relevant campaign issues. Users were also presented with numerous highlights, which included a wide range of videos from stump speeches, news interviews, campaign advertisements, media parodies, and audience-reaction and user-generated videos.

By serving as a fully functioning social video tracker and providing analytical data, the YouTube Politics Channel made it easy for users to keep connected to the digital political pulse of the 2012 presidential election, with over 35,000 subscribers and over 4 million video views.

YouTube War

The idea of a "YouTube War" has been applied to a few conflicts since the 2005 creation of the Web site YouTube.com. The earliest uses seem to be regarding the Iraq War that started in 2003, and refer to postings of YouTube videos by soldiers showing what conditions in various Iraqi cities were actually like.

The term came to be used in the 2011 Libyan civil war, both in reference to the war's initial catalyst, the Benghazi protests of killed prisoners' relatives posted on YouTube and then broadcast by Al Jazeera television, and in reference to the ongoing use of YouTube during the conflict to document casualties and attacks.

Libyans celebrating in Al-Keish Square in Benghazi on October 23, 2011, after the fall of the dictatorship and death of Muammar Qadhafi at the hands of rebel forces. While Internet access had only reached 17 percent of the Libyan population when the uprising began, activists, especially from the Libyan diaspora, were able to spread YouTube videos and other online images of the oppression of Libyan protesters. This drew international outrage that likely hastened the end of the conflict.

Timeline

In March 2010, several relatives of prisoners killed at Abu Salim prison gathered to protest against the government of Muammar Qadhafi. The government response to these peaceful gatherings was to disperse them through violence, including the use of snipers to target people in the crowds. As word of the protests spread, a wholesale censorship campaign was undertaken to block Internet and telephone access throughout Libya in an effort to limit the potential of the protests to spread. The censorship began with blocking access to opposition political Web sites, and eventually included a blockade of all YouTube videos, not only because of the videos uploaded from the mobile phones of protest attendees, but also because of other videos showing various members of Qadhafi's family attending lavish parties. This provided a visceral reminder of the privileged lifestyle enjoyed by the

regime and their estrangement from the difficult economic realities faced by most Libyans.

Beginning in February 2011, Libyans launched a series of protests against the Qadhafi regime that were sparked by the arrest of a prominent human rights activist, Fethi Tarbel. By the end of the month, rebel militias had taken control of Misrata and portions of Benghazi. The government responded by attacking protesters using aircraft and other methods widely considered disproportionate by the international community. Despite the Internet ban, these images and many others quickly made their way onto international Web sites and televisions through satellite news services like Al Jazeera, al-Arabiya, CNN, and others.

Organizations like Human Rights Watch demanded that the Libyan government re-establish access to opposition sites and YouTube and allow for transparency in order to afford some

level of protection via publicity to protesters and rebels. This was complemented by international sanctions, including a March 17 United Nations (UN) Security Council resolution authorizing a no-fly zone over Libya and the proactive military defense of civilian populations.

NATO forces were quickly invoked to enforce the UN resolution and engage in attacks on Libyan government forces deemed threatening to civilians. During March and April, the conflict quickly evolved from civilian protests to full-scale civil war, with rebel militias and government forces vying for control of key towns and power centers. Defections of various military units and government ministers quickly exposed the vulnerabilities of the regime.

A major development occurred in July when the National Transitional Council (NTC) was recognized as the legitimate representative of the Libyan people by the International Contact Group (ICG) on Libya. Throughout the summer, rebel groups continued to gain territory, until they finally entered Tripoli and Qadhafi's compound in August. Many major states followed the lead of the ICG and also recognized the NTC as the legitimate government during August and September. On October 20, Qadhafi was captured and killed by rebel forces.

Throughout the war, major developments, human rights abuses, protests, and declarations from various rebel groups were frequently uploaded to YouTube and then rebroadcast by various news outlets. These reports often noted that footage could not be verified, but it was nonetheless aired and treated as relatively reliable. In a sense, this made the Libyan civil war and Libyan revolution the first such conflict to be filmed primarily by amateurs using mobile phones at the scenes of various events.

YouTube Libyan Civil War Channel

In addition to television news, many of those who regularly uploaded videos of the Libya conflict created YouTube channels, which could then attract subscribers who would receive updates when new content was posted. It also allowed for users to leave comments in the footer of each clip, and to share videos on social networking sites like Facebook and Twitter. In May 2013, these channels contained roughly 500 unique videos. These fell

into various categories. Primarily, they consisted of amateur recordings of attacks as they occurred, generally from a viewpoint supportive of the rebel groups and the NTC. Another significant number of videos featured public pronouncements by various officials in major governments and international bodies, including President Obama, former U.S. Secretary of State Hillary Clinton, and former U.S. Secretary of Defense Leon Panetta. Responses by officials in the Qadhafi regime, including his son Saif al-Islam Qadhafi and their supporters, also featured frequently noting abuses and humanitarian violations supposedly committed by the rebels and NATO. A few of these were uploaded news interviews with Muammar Qadhafi. A third, though significantly less numerous, group of clips involves the interpretation of various foreign policy experts and academics on the developments in Libya as they occurred, the justification or lack thereof for intervention, and the potential for democracy in a post-Qadhafi state. Finally, a small number of videos included individual commentary on the conflict in the form of video blogs, or even protest songs.

One of the most highly viewed of these videos was a post uploaded by Al Jazeera English during the most intense months of fighting, which is titled *Visual Diary Shows Libyan Soldier at War*. This three-and-a-half-minute short film includes footage of traveling in rebel convoys, posed photographs with weapons, interactions with NATO troops, and extremely graphic images of dead bodies, which appear to include both civilians and rebel fighters. The smiling face of the young soldier preparing for battle is made poignant with the subtitle noting that the soldier who filmed the footage was subsequently killed in battle.

Assessments

Some assessments of the Libya conflict argue that the significance of social media is easily overstated in terms of its impact on the local population and the spread of the conflict. Local Internet access had reached a penetration of only 17 percent of the population at the time the uprising began. Likewise, there were only 200,000 active Facebook and 64,000 active Twitter accounts in the country at the time. Research has shown that the vast majority of use of these sites were simply

used for personal relationships. However, a relatively large Libyan diaspora publicized abuses of the Qadhafi regime based on reports from friends and family, and launched a “day of anger” online, which also marked the true start of the revolution on February 17, 2011. They were instrumental in creating a viral video phenomenon by sharing videos uploaded by people in eastern Libya who were participating in or affected by the uprisings. Thus, YouTube and sites like Facebook were far more influential in galvanizing public opinion outside Libya than they were in coordinating or motivating the rebellion within.

Crucially, the easy access to YouTube clips meant that populations of powerful and influential states, including those on the UN Security Council, were confronted with frequent and shocking reminders of the brutality of the Qadhafi regime. This meant that the conflict quickly gained a human face, and the prospect of wholesale slaughter of civilians was taken seriously and treated with the utmost urgency.

As the timeline of the conflict reveals, the transition from the Western embrace of the Qadhafi regime, to its request for human rights to be respected, to the ultimate economic sanctions and virtual declaration of war happened in a matter of just a few months. It is difficult to imagine that absent this viral video component, abetted by social media, that the attention of the rest of the world would have been so fixated on this relatively isolated and poor country.

Of course, the CNN effect, or Al Jazeera effect, which note the role of television media in bringing war into the living rooms of viewers and changing the way that citizens and politicians react to conflict, could easily apply to this case. The difference, however, is that CNN, Al

Jazeera, and other broadcasters were not able to take their cameras into the west of the country, or into all the many conflict zones, meaning that uploaded YouTube clips became the most important primary sources for reporting, especially in terms of visual impact.

Z

Zuckerberg, Mark

Cofounder, chairman, and CEO of Facebook, Mark Elliot Zuckerberg was born May 14, 1984, to Edward and Karen Zuckerberg in White Plains, New York. Both parents were well-educated. His father is a practicing dentist, and his mother is a licensed psychiatrist. The couple had four children—Mark, Randi, Donna, and Arielle. Although several sources report that Zuckerberg characterizes himself as an atheist, he was raised Jewish. Growing up in a Jewish family, Zuckerberg celebrated his *Star Wars*-themed bar mitzvah at Temple Beth Abraham under Rabbi David Holtz. The *Greenburgh Daily Voice* reported that Zuckerberg was a typical kid in the 1990s, enjoying extracurricular activities at Ardsley Middle School, including cross-country and fencing. Zuckerberg's Facebook timeline reports that he attended Ardsley High School for two years before transferring and graduating from Phillips Exeter Academy.

In his early adolescence, Zuckerberg enjoyed tinkering with computers and writing software. His father taught him some skills of programming early on, until he hired David Newman to tutor his son. Newman later told reporters that Zuckerberg was a prodigy. While his peers were playing computer games, Zuckerberg was creating computer software programs. Among his

first software programs was ZuckNet, which allowed users to message each other. Many claim that his father was his first client, using the program in his dental practice. He also built Synapse Media Player, a program that would monitor user's listening habits and in turn recommend music based on what the user liked. He was approached by Microsoft to purchase the entity, but declined.

In 2002, Zuckerberg enrolled at Harvard University to major in psychology and computer science. In his second year at Harvard, Zuckerberg created two different software programs. The first was called CourseMatch, and aimed to help students make class selections and form study groups. The second was called Facemash, a program that allowed students to self-select the best looking person from photos. Journalist Nicholas Carlson notes, "Mark got in trouble for creating it. The way the site worked was that it pulled photos of Harvard students off Harvard's Web sites. It rearranged these photos so that when people visited Facemash.com they would see pictures of two Harvard students and be asked to vote on which was more attractive." Although Zuckerberg was disciplined, he was not expelled from the school.

Although controversy exists over how the idea came about, Zuckerberg is most known for his creation of the Web site Facebook. Some argue

President Barack Obama and Facebook CEO Mark Zuckerberg discussing social media and politics at a “Facebook Live” town hall event held at Facebook’s headquarters in Palo Alto, California, on April 20, 2011. The public was able to submit questions to the president via Facebook wall posts or the White House Web site, and the event was then livestreamed to online viewers on Facebook.

that Harvard seniors Cameron Winklevoss, Tyler Winklevoss, and Divya Narendra generated the idea for the social network HarvardConnections.com, and asked Zuckerberg to join their team and create the coding for the program. The three filed a lawsuit against Zuckerberg for stealing their idea. In April 2008, they were awarded \$20 million cash and \$45 million in stock in a settlement. In April 2011, the Winklevoss twin brothers appealed the case in the 9th U.S. Circuit Court of Appeals, but were denied an overturn of the initial lower court’s ruling.

Facebook

Started in Zuckerberg’s Harvard dorm room in February 2004, thefacebook.com was originally only for use by Harvard students. Pulling in his Harvard friends Chris Hughes, Eduardo Saverin, and Dustin Moskovitz, the four expanded the site to include other Ivy League schools, and then expanded to other university, high school, and international

campuses. The domain name, Facebook.com, was reportedly purchased for \$200,000. In 2006 Facebook exploded, and was opened to anyone 13 years and older with an e-mail address. Headquartered in Menlo Park, California, Facebook’s newsroom reports that 4,600 employees currently work for the company. It also boasts that as of October 2012, more than 1 billion people were active on Facebook, with 618 million daily active users.

Zuckerberg Ties the Knot

On May 19, 2012, Zuckerberg married Priscilla Chan in a small backyard ceremony at Zuckerberg’s Palo Alto home. He told the rest of the world by simply updating his Facebook status to “married.” According to *People* magazine, Chan and Zuckerberg met in college at a fraternity party, as both attended Harvard. According to her Facebook page, Chan is a native of Braintree, Massachusetts, and went to Quincy High School, graduating in 2003. A biology major, Chan graduated

in 2007 from Harvard University. After a brief stint teaching middle-school children, Chan continued her education, and in 2012, she graduated from the University of California, San Francisco medical school.

Political Activism

In September 2011, Zuckerberg's Facebook company created a political action committee (PAC) to focus on the election cycle and lobby for support regarding privacy and patents. Facebook had been trying to raise its profile in Washington, D.C., since the hiring of Chief Operating Officer Sheryl Sandberg in 2008. *CNN Money* reported in October 2012 that Facebook's PAC had raised a great deal of money. Although the company's employees heavily favor Democrats through their personal contributions, the social media company awarded Republicans \$13,000 more than Democrats through the end of September 2012.

In April 2013, Zuckerberg, along with well-known leaders in the technology community, unveiled a new bipartisan political advocacy group Fwd.us. According to Evelyn Rusli in a *Wall Street Journal* article, Zuckerberg highlighted three priorities for the group:

Comprehensive immigration reform that provides a clear path to citizenship; education reform to press for higher standards in schools and a "much greater focus" on math and sciences; and increased investment for scientific research.

Zuckerberg and his wife have also participated in political fundraising. In February 2013, the couple held a fundraising event at their home in Palo Alto for New Jersey Governor Chris Christie's re-election.

Philanthropy

In March 2013, Mark Zuckerberg's net worth was reported by *Forbes* as \$13.3 billion. *The Chronicle of Philanthropy* listed Zuckerberg and his wife as the second-largest charitable donors in the United States for 2012. Zuckerberg is one of the American billionaires who have committed at least half of their wealth to charity during their lifetimes through a philanthropic campaign called the Giving Pledge. Leaders and U.S. billionaires Warren

Buffett and Bill Gates launched the campaign in 2010. During the holiday season of 2012, Zuckerberg gifted 18 million Facebook shares to the Silicon Valley Community Foundation for education initiatives that were worth nearly \$500 million.

Glossary

Above the fold: On a Web page, content that can be seen without scrolling.

Absolute URL: Also called an absolute link, an Internet address that takes a user to the exact location of a file on the Internet.

Active time: Also known as engagement time, the amount of time a visitor to a Web site spends interacting with the page, for example, by clicking, scrolling, or hovering.

Ad banner: A type of Internet ad appearing on the top or bottom of a Web page.

Ad pages sold: The number of page views sold to an advertiser by an Internet advertising firm.

Adobe Acrobat: Software that allows users to create and read files in portable document format (PDF), a format that allows them to be shared, but prevents them from being changed.

AdWords: An advertising program created by Google that allows Web site owners to earn revenue by displaying ads next to their online content; the ads are selected to match audience interests, and the Web site owner earns money when a user clicks on an ad.

Aid Still Required (www.aidstillrequired.org): An organization founded by Andrea Herz Payne to bring continued awareness to issues (e.g., the conditions in a country months after a natural disaster) that may have fallen out of the news spotlight, but for which charitable support is still needed.

AIDA: Attention, interest, desire, and action—a traditional model for how advertising works, by moving a person from attention through interest and desire to action.

Alert: A media tool such as Google Alerts or Social Mention that sends notifications to a user when particular words or phrases (e.g., a company name or personal name) are mentioned on the Internet.

Amplification: One of the three components of a Klout score, amplification refers to how many people to act on messages posted by an individual.

App: A limited-use computer application that can be downloaded from the Internet.

Banner exchange: A type of Internet advertising in which different Web sites display each other's banner ads.

Blind link: A link on a Web page that does not indicate to the user where clicking on it will take them.

Blawg: A blog about the law.

Blog: A journal kept on the Internet for personal or other purposes; a contraction of “Web log.”

Blogroll: A list of blogs recommended on a blog or other Web page, typically on topics related to the Web page and carried as a vertical list on one side of the Web page.

Born This Way Foundation: A foundation created in 2011 by pop singer Lady Gaga and her mother, Cynthia Germanotta, to help create a society tolerant of individual differences, particularly but not exclusively around gender and sexuality, and in which young people feel empowered to build a better world.

Bounce: A visit to a Web site in which the user views only one page.

Bounce rate: The number of bounces divided by the number of visits to a Web site.

Button ad: A small advertisement on a Web page, usually a small circular or rectangular ad at the bottom of the page.

Buzz: A rough measure of the number of people talking or tweeting about a product or candidate; campaigns may aim at “creating buzz,” meaning a goal to increase the number of people aware of something and talking about it.

Call to action: The part of an advertisement that asks the reader to do something specific.

CAPTCHA (Completely Automated Public Turing Test to Tell Computers and Humans Apart): an anticomment spam feature that requires users to type in the characters appearing in a window (often in distorted form, to defeat optical character recognition) before posting.

Chiclet: A type of computer keyboard in which the keys are raised and separated by spaces, so the keys look like pieces of Chiclets gum.

Alternatively, the small, square graphics appearing on Web and social media screens that display the logos of various RSS feeds and social media providers, such as the now-famous symbols for Twitter and Facebook. They are used on Web pages and social media apps to help providers track content as it moves around the digital universe, and to improve interconnectivity among different types of platforms.

Churn rate: The proportion of subscribers who leave a service (e.g., a mobile phone company). Also, the period of time it takes for a specific piece of hardware or software to become obsolete because of changes in regulatory policy, changes in technical standards and/or technology, or by corporate fiat on the part of the technology provider (e.g., discontinuing support for a particular platform or storage device).

Click path: The sequence of clicks that a visitor follows on a particular Web site.

Comment spam: Spam posted in the comments section of a blog, often posted by spambots; the CAPTCHA (Completely Automated Public Turing Test to Tell Computers and Humans Apart): system was developed to try to prevent comment spam.

Content provider: In the context of the Internet, an individual or company that provides content, such as text and graphics, to be posted on a Web site.

Contextual advertising: Advertising matched to the hosting Web page, usually by using keywords.

Conversion: When a reader takes a desired action, such as making a contribution, after viewing a web page or clicking on an ad.

Conversion rate: The number of conversions divided by the number of page views or clicks.

CPM: Cost per thousand, a method of paying for advertisements in terms of the number of impressions made on an ad, for example, \$5 per 1,000 impressions.

CRM: Customer relationship management, a model that uses technology to manage the

interactions between a company and its customers, prospects, and so forth.

CTR: Click-through rate, the number of people who, after reading an ad, click on it.

CU-SeeMe: A free videoconferencing program that allows individuals to use a video camera and Internet connection to exchange live video.

DailyKos.com: A popular political Web site founded and published by Markos Moulitsas Zuniga in May 2002; as of 2012, the site had a quarter of a million registered users and 2.5 million unique visitors each month.

Deliverability: In the context of e-mail, the ability to deliver e-mail to the intended recipients.

Delivery rate: The percentage of e-mails in a marketing campaign that are received in the recipient's inbox, rather than their spam folder.

Digital divide: A term referring to differences in Internet access (or broadband access) among people of different races, genders, social classes, and so forth. Increasingly refers in a more generalized way to one's degree of access to the full range of mobile and online technology and resources.

Direct traffic: Users that come to a Web site by entering the URL.

Dooce: Being fired for something done on the Internet; the term was coined in 2002 by Heather Armstrong, who wrote about her job on her blog Dooce.com.

EMS: Electronic meeting system, a platform to facilitate group meetings over the Internet.

Event blog: A blog created to promote an event, or to otherwise present content about a specific event.

Exit percentage: The total number of exits (people leaving a Web page) divided by the number of pageviews.

Expert influencer: Someone who exerts influence on others because he or she is recognized as

an authority, even if he or she is not personally known to the person who is influenced.

Facebook: A social networking site created in 2004 by Mark Zuckerberg, now the largest social networking site on the Internet.

FeedReader: A news aggregation program that allows readers to collect news feeds and access them from the Internet or a mobile device; more generally, a "feedreader" or "feed reader" is any program providing this type of capability.

Flame: posting a hostile comment in response to an online article or blog post; flames are often based on personal attack, rather than engagement with the issues.

Follower: In the context of Twitter, a subscriber to the tweets of another person or organization.

Following: In the context of Twitter, choosing to "follow" someone means that one will receive their tweets (Twitter messages).

Forum: An online discussion site where people can post messages and reply to other messages; also known as a message board. Forums are usually organized into topics, and the messages are archived.

Friending function: On Facebook and similar social networks, sending an invitation to another Facebook user, inviting them to be a "friend," or giving them the choice to accept, decline, or defer. For example, it is possible to limit Facebook posts or other activities like sharing music to only friends.

Geolocation: The ability to identify the geographic location of an object.

Geolocational enabling: Turning on the function (e.g., on a mobile phone or computer) that allows software to deduce its location, for instance, so it can suggest restaurants in the vicinity.

Geotargeting: Choosing which content or advertising will be displayed to a user, based on his or her geographic location.

Google Groups: A social media service provided by Google to help readers find discussion groups related to their interests; it began as Deja News in 1995.

Haloscan: An early blog comment hosting service, founded in 2002, and renamed Echo in 2009.

Hashtag: A word or phrase (with no spaces) preceded by the # symbol, such as #ivoted; hashtags are used on Twitter to make it easy for users to find related content.

Hat tip: Acknowledgement of another's assistance; for instance, in providing the original idea for a blog post.

High consideration purchase: A purchase involving a relatively large amount of money, and hence relatively high risk; for instance, a new car.

Hit: A request to a Web server for a file to be uploaded.

Hotspot: A picture or icon that is hyperlinked. Also refers to particularly useful social media points at which to gather user or viewer metrics, as well as to places in the physical environment where wireless Internet service is available.

HTML: Hypertext markup language, a coding language used on the Internet to create Web pages.

HTTP: Hypertext transfer protocol, a set of rules allowing communication among computers connected to the Internet.

Hyperlink: On the Internet, a reference to another Web site or other data (e.g., a document) that can be accessed by clicking on the link.

ICQ: "I seek you," an instant messenger service that can be used online or with a smartphone.

Impression: In Internet advertising, a single display of an advertisement on a Web page.

Inbound links: Links from other sites on the Internet to your Web site; a high number of inbound

links is one of the factors that may give a Web site a high ranking for search engines.

Infoglut: A mass of poorly organized information that is difficult to productively use.

Interstitial advertising: A type of Internet ad that appears during the transition from one Web page to another.

IPTV: Internet protocol television, a method of delivering television programs to viewers over the Internet.

Joined-up marketing: Creating a consistent brand strategy across all the different ways a customer may become aware of or interact with a company, including e-mail marketing, direct mail marketing, Internet advertising, or a Facebook app.

Keyword density: The ratio of a particular keyword to the total number of words on a Web page.

Keyword stuffing: A practice in which a keyword is inserted many times into a page in order to increase the page's keyword density.

Klout: A measure of social influence, ranging from 1 to 100, with higher scores indicating stronger influence and ability to cause others to take action. A Klout score is made up of three parts: true reach, amplification, and network impact.

Landing page: The Web page first shown to a visitor who arrives from another site; landing pages are usually specific to a given referring link.

Like function: On Facebook, the ability for a user to click a button on a Web site to indicate that they "like" a posting or a site, that is, are a fan of the item; however, "like" fraud is also possible, because the like button may be linked to a different Web site than the one where the button resides.

List cleaning: Also known as list scrubbing or list pruning, removing e-mails (or postal mail addresses) that are incorrect, undeliverable, or duplicated.

Liveblogging: Providing an ongoing series of blog posts during an event (e.g., an election or sporting event) to provide news coverage and commentary.

Low consideration purchase: A purchase involving relatively little money and relatively little risk; for instance, toothpaste.

Lurking: Reading content on an online forum or e-mail list without posting to the discussions.

Malware: Malicious software that may be installed on a user's computer without his or her knowledge, such as spyware.

Meetup: A social networking portal intended to help people meet others with like interests in their geographical area and organize group meetings.

Metadata: Literally data about data; 15 elements were defined as essential metadata for resource description at a workshop held in Dublin in 1995, and are known as the Dublin Core Metadata Element Set.

Microblog: A blog that limits file size, for instance, limiting a post to single images or short text messages. Twitter is a form of microblog.

Mobile application: An application designed for a mobile device, such as a smartphone.

MP3: A compression and playback standard for digital audio files.

Narrowcasting: Delivering a message to a specific group of people.

Netroots: Political activism organized through online social media, such as wikis and blogs; the term was coined in 2002 by Jerome Armstrong, an American political strategist.

Network impact: One of the three components of a Klout score, network impact refers to how often key influencers respond to content.

News reader: An Internet application on Usenet that allows readers to download, read, and post to Usenet groups.

NPTech: Information related to nonprofits and technology.

Open rate: In the context of an e-mail marketing campaign, the percentage of message or advertising e-mails actually opened by the people who receive them.

Opt-in: Features such as e-mails that are only provided to individuals who indicate that they want to receive them.

Organic search results: Site listings resulting from a user performing a search, as opposed to clicking on an ad.

Over-building: Building more computer capacity than is expected to be needed, so that necessary capacity will be available, even if there are failures of hardware or software.

Page depth: Also known as page views per session, the average number of page views by a visitor during a session.

Page tagging: Placing a piece of JavaScript code on a Web page to collect information about people who visit that page.

Pageview: A unit of measurement referring to one person looking at one Web page.

Peer influencer: *See* Positional influencer.

Permalink: A permanent URL linking to a Web page, document, and so forth, that will remain valid even if the original location of the Web page is moved.

Person finder: A Google Web application built in 2010 after the earthquake in Haiti to help people locate friends and relatives after that and similar disasters.

Phishing: Using fraudulent means to obtain confidential information such as usernames and passwords, for example, by sending an e-mail purportedly from an individual's bank and asking for their account information in order to "restore service."

Ping: A message sent by a blog to a server when a new entry is posted or updated.

Poke: On Facebook, to send a message to attract the attention of someone, analogous to physically poking them.

Pop-under ads: Also known as pop-behind ads, ads that automatically appear in a new window behind the current window when a user visits a Web site or clicks on an ad.

Pop-up ads: Ads that automatically appear in a new Web window on top of the current window when a user visits a Web site or clicks on an ad.

Positional influencer: Someone who exerts influence through their relationship with the individual being influenced; for example, by being a member of the same family or a close friend. Also known as peer influencers.

Posting: To send a message to an Internet forum, blog, or in a section devoted to comments on news or other Web pages.

Power user: Someone who is unusually good at using a computer program and can use advanced features of the program.

PPC advertising: Pay-per-click advertising, a type of advertising in which the advertiser only pays when a visitor actually clicks on an ad.

Product placement: Arranging for a product to be seen or mentioned on a Web site or in a film or television show, appearing to be a normal part of the story, but in fact as a means of advertising the product.

PSA: Public service announcement, an announcement usually run at no cost because it is considered to be in the public interest.

Real World: A reality television program running on MTV beginning in 1992; one of the first of many reality shows, it followed a group of strangers who live together in a house and depicts many issues relevant to young adults, such as sexuality and drug use.

Reblog: Reposting content written by someone else, with the notice that it originated elsewhere; reblogging has become an indicator of the popularity of posts on social media sites.

Recency: The number of days passed since a given user has visited a given Web site.

Red-lining: Also known as “weblining,” a method of grading customers and allocating resources toward them. Alternatively, the act of omitting entire populations from the list of those slated to receive infrastructural improvements related to new technologies (such as high-speed fiber optical cable replacing in-ground copper wiring) by simply crossing them out on the relevant lists in policymaker and/or provider development activities. Often determined by geographical location, economic status, “need for service,” and/or “perceived ability to pay” criteria.

Redundancy: In Internet terms, having a secondary system to back up service in case of a failure in the primary service.

Referent influencer: Someone who exerts influence on people who he or she knows, whether in person or through the use of social media.

Referring site: A Web site that sends a user to another site.

Repeat visitor: A user who makes at least two visits to a given Web site.

Retweet: Forwarding or posting someone else’s tweet (Twitter message).

ROI: Return on investment, a measure of evaluating the effectiveness of an advertising campaign or other business decision; ROI is calculated by dividing the return (e.g., contributions received) by the cost of whatever is evaluated.

Search engine: A tool to find information on the Internet by entering search terms; major search engines include Google, Yahoo!, and Bing.

Secure mobile phone messaging: Using software to encrypt SMS text messages sent via mobile phone.

SEO: Search engine optimization, a method of manipulating content on a Web site in order to have that site rank more highly in searches and thus become more visible.

Session: A theoretically uninterrupted visit by a user to a Web site, during which time the user does not go to any other Web site, and there is not a gap of 30 minutes or longer between pageviews.

Signal blocking: Blocking a wireless signal by electronic (i.e., jamming) or physical (i.e., wallpaper with metallic ink) means.

SIM: Social influence marketing, that is, using social media in a marketing campaign.

Single: A visit to a Web site during which a user views only one Web page.

Skyscraper ad: A vertical display ad, usually appearing on one side of a Web page.

Sleeper effect: An observed psychological effect in which a message paired with a discrediting cue (e.g., the information comes from a disreputable source) becomes more, rather than less, persuasive in a person's memory over time.

SMS: Short messaging service, a method to send short text messages using a mobile phone, the Internet, and so forth.

Snoball.com: A Web site to encourage people to donate to charities; users choose from a number of charities (1.7 million as of November 2012) and make specific pledges based on their behavior (e.g., contributing a set amount to a charity each time they patronize a particular coffee shop) or external event (e.g., making a specific donation each time a particular sports team wins).

Social blogs: Blogs created to share personal information about the blogger.

Social conversation: A type of social marketing in which a brand engages in a direct conversation with customers or potential customers through social media such as Twitter or Facebook.

Social influencers: People who have an unusually strong influence on their peers, in matters ranging from consumer choices (e.g., what brand of clothing they favor or what television programs they watch) to casting a vote in an election.

Social network: A Web site that facilitates users connecting with each other and sharing information; Facebook is currently the largest social network in the world.

Social news service: Also called a social bookmarking service, a service that facilitates sharing of Web pages with friends.

Spam: E-mail that is neither requested nor desired by a user; much spam carries unsolicited advertising, hence the alternate name unwanted commercial e-mail (UCE).

Splog: A spam blog, that is, a blog created solely to make money from advertisers by garnering pageviews from users coming from search engines; the articles in splogs are often made up primarily of search terms in order to attract more clicks.

Spyware: Malware (malicious software) that captures information from a computer without the user's knowledge.

Super-user: A system administrator granted privileges to make changes in the systems beyond what ordinary users are allowed to do.

Tablet: A small mobile personal computer with a touch screen and a virtual keyboard.

Tag cloud: A graphical display of tags or important words in a document, with terms used more often presented in larger type.

Tags: Keywords assigned to documents or images on the Internet, so that the Web pages can be more easily found by search engines.

Technology steward: A person who understands the technology needs of a community and has sufficient expertise to address them. Often plays a gatekeeper role for technologically unsophisticated populations.

Thread: On a message board, the sequence of messages in response to an initial post.

Tiananmen Square tank video: Video of the Tiananmen Square protests in Beijing, China, in 1989, including a man facing down Chinese tanks; the video was widely viewed internationally.

Trackback: A method of notifying an Internet author when someone links to a document created by him or her.

Troll: On the Internet, someone who disrupts an online community by posting off-topic or inflammatory messages.

True reach: One of the three components of a Klout score, true reach represents the number of people influenced by one person.

Tweeps: In the context of Twitter, people who follow someone else's tweets.

Tweet: Text messages sent on Twitter; they must be 140 characters or fewer.

TweetReach: A company specializing in analyzing the impact of Twitter campaigns.

Tweetup: An in-person meeting by people who usually communicate over Twitter.

Twitter: A social messaging tool that allows users to post brief text messages (140 characters or fewer) called tweets.

Unconnected: People who do not have ready access to high-speed Internet and/or mobile and social media resources, or who elect not to use those resources even if they are available.

Unique visitor: In Web analytics, a person who visits a Web site at least once in a given period of time; a unique visitor is counted only once, even if they visit the Web site multiple times during the given time period.

Unsubscribe/opt-out: Choosing to not be part of an e-mail list.

URL: Uniform resource locator, a character string identifying a Web site.

Viral: In the Internet context, to become extremely popular in a short period of time; a video or Web page that is viewed by many people (sometimes millions) in a short period of time is said to have "gone viral." Typically, content must migrate from its original distribution platform to other communication modalities in order to achieve viral status.

Virtual world: An online community formed around a computer-simulated environment, such as that typical of multiplayer fantasy games.

VOIP: Voice over internet protocol, a method of transmitting voice communications, faxes, etc., over the Internet rather than over phone lines.

VPN: Virtual private network, a private network transmitted over the Internet.

Warm traffic: In terms of marketing, people who know in general what they want, but do not know that your product will solve their problem.

Web analytics: The analysis of data collected from the Internet, often done to optimize a Web site.

Web spider: Also called a Web crawler, a search engine that locates information on the Internet in a systematic fashion by browsing the Web at regular intervals and indexing all the words in documents located.

Webcast: The broadcast of a live event over the Internet.

Widgets: Software applications designed to be portable so they can run on multiple software platforms.

Wiki: A Web site that allows multiple users to add, edit, and delete content, thus promoting cooperation in the creation of documents and other content.

Wonkette: An online satirical political magazine founded in 2004 by Gawker Media.

XML: Extensible markup language, a document description language for the Internet that was standardized in 1998.

YouTube: A video-sharing site created in 2005, and currently owned by Google.

Appendix

Congressional Social Media Use

Compiled by J. Thomas Walzer

There is no doubt that social media has generated a new era in political communication, especially among representative lawmakers and their constituents. But how far the social media phenomenon has developed can only be seen on a case-by-case basis as presented in the following statistics. Seeing the kind of editorial research done at SAGE's sister publication, *CQ Researcher* (www.cqresearcher.com), this encyclopedia's editors undertook the challenge of determining exactly what U.S. Congresspersons were up to on the social media front. Using *CQ Researcher* as a starting point to contact office managers, administrative heads, or communication managers for each Congressperson, we created the following appendix detailing individual representatives' number of Facebook "likes," average Facebook post frequency, number of tweets, number of Twitter followers, YouTube usage, and number of videos posted, among other social media uses. The appendix was researched in October 2013, at the latest possible date prior to the encyclopedia's to-press deadline in early November.

The results of the research clearly indicate Senator John McCain (R-Arizona) is among the leaders of the pack with 862,382 Facebook "likes," 1,817,626 Twitter followers, and 603 videos posted on YouTube. Yet McCain does not have an RSS feed. Closer to the lower end of the spectrum in the U.S. House of Representative, there is Representative C. W. Bill Young (R-Florida) with 33 Facebook "likes" and no Twitter account. We included the birth date and age of the Congressperson to see if there was any correlation between social media activity and age. We leave that to the reader to deduce.

—*The Editors*
